NATIONAL BUREAU OF ECONOMIC RESEARCH

1963

OFFICERS

Harold M. Groves, *Chairman*
 Arthur F. Burns, *President*
 Albert J. Hettinger, Jr., *Vice-President*
 Donald B. Woodward, *Treasurer*

Solomon Fabricant, *Director of Research*
 Geoffrey H. Moore, *Associate Director of Research*
 Hal B. Lary, *Associate Director of Research*
 William J. Carson, *Executive Director*

DIRECTORS AT LARGE

Robert B. Anderson, *New York City*
 Wallace J. Campbell, *Nationwide Insurance*
 Erwin D. Canham, *Christian Science Monitor*
 Solomon Fabricant, *New York University*
 Marion B. Folsom, *Eastman Kodak Company*
 Crawford H. Greenewalt, *E. I. du Pont de Nemours & Company*
 Gabriel Hauge, *Manufacturers Hanover Trust Company*
 A. J. Hayes, *International Association of Machinists*
 Albert J. Hettinger, Jr., *Lazard Frères and Company*

Nicholas Kelley, *Kelley Drye Newhall Maginnes & Warren*
 H. W. Laidler, *League for Industrial Democracy*
 George B. Roberts, *Larchmont, New York*
 Harry Scherman, *Book-of-the-Month Club*
 Boris Shishkin, *American Federation of Labor and Congress of Industrial Organizations*
 George Soule, *South Kent, Connecticut*
 Joseph H. Willits, *Armonk, New York*
 Donald B. Woodward, *A. W. Jones and Company*
 Theodore O. Yntema, *Ford Motor Company*

DIRECTORS BY UNIVERSITY APPOINTMENT

V. W. Bladen, *Toronto*
 Arthur F. Burns, *Columbia*
 Lester V. Chandler, *Princeton*
 Melvin G. de Chazeau, *Cornell*
 Frank W. Fetter, *Northwestern*
 R. A. Gordon, *California*
 Harold M. Groves, *Wisconsin*
 Gottfried Haberler, *Harvard*

Walter W. Heller, *Minnesota*
 Maurice W. Lee, *North Carolina*
 Lloyd G. Reynolds, *Yale*
 Paul A. Samuelson, *Massachusetts Institute of Technology*
 Theodore W. Schultz, *Chicago*
 Willis J. Winn, *Pennsylvania*

DIRECTORS BY APPOINTMENT OF OTHER ORGANIZATIONS

Percival F. Brundage, *American Institute of Certified Public Accountants*
 Harold G. Halcrow, *American Farm Economic Association*
 Theodore V. Houser, *Committee for Economic Development*

Murray Shields, *American Management Association*
 Willard L. Thorp, *American Economic Association*
 W. Allen Wallis, *American Statistical Association*

Harold F. Williamson, *Economic History Association*

DIRECTORS EMERITI

Shepard Morgan, *Norfolk, Connecticut*

N. I. Stone, *New York City*

RELATION OF THE DIRECTORS TO THE WORK AND PUBLICATIONS
OF THE NATIONAL BUREAU OF ECONOMIC RESEARCH

1 The object of the National Bureau of Economic Research is to ascertain and to present to the public important economic facts and their interpretation in a scientific and impartial manner. The Board of Directors is charged with the responsibility of ensuring that the work of the National Bureau is carried on in strict conformity with this object.

2 To this end the Board of Directors shall appoint one or more Directors of Research.

3 The Director or Directors of Research shall submit to the members of the Board, or to its Executive Committee, for their formal adoption, all specific proposals concerning researches to be instituted.

4 No report shall be published until the Director or Directors of Research shall have submitted to the Board a summary drawing attention to the character of the data and their utilization in the report, the nature and treatment of the problems involved, the main conclusions, and such other information as in their opinion would serve to determine the suitability of the report for publication in accordance with the principles of the National Bureau.

5 A copy of any manuscript proposed for publication shall also be submitted to each member of the Board. For each manuscript to be so submitted a special committee shall be appointed by the President, or at his designation by the Executive Director, consisting of three Directors selected as nearly as may be one from each general division of the Board. The names of the special manuscript committee shall be stated to each Director when the summary and report described in paragraph (4) are sent to him. It shall be the duty of each member of the committee to read the manuscript. If each member of the special committee signifies his approval within thirty days, the manuscript may be published. If each member of the special committee has not signified his approval within thirty days of the transmittal of the report and manuscript, the Director of Research shall then notify each member of the Board, requesting approval or disapproval of publication, and thirty additional days shall be granted for this purpose. The manuscript shall then not be published unless at least a majority of the entire Board and a two-thirds majority of those members of the Board who shall have voted on the proposal within the time fixed for the receipt of votes on the publication proposed shall have approved.

6 No manuscript may be published, though approved by each member of the special committee, until forty-five days have elapsed from the transmittal of the summary and report. The interval is allowed for the receipt of any memorandum of dissent or reservation, together with a brief statement of his reasons, that any member may wish to express, and such memorandum of dissent or reservation shall be published with the manuscript if he so desires. Publication does not, however, imply that each member of the Board has read the manuscript, or that either members of the Board in general, or of the special committee, have passed upon its validity in every detail.

7 A copy of this resolution shall, unless otherwise determined by the Board, be printed in each copy of every National Bureau book.

(Resolution adopted October 25, 1926, as re-used February 6, 1933, and February 24, 1941)

Acknowledgments

THE author's balance sheet, at the conclusion of this study, records a heavy weight of indebtedness to colleagues, assistants, and others

Solomon Fabricant first suggested the subject for study and supplied advice and encouragement as the work progressed. Albert O. Hirschman and Ilse Mintz contributed many stimulating ideas regarding the questions to be asked and the organization of the answers. Other valuable comments and suggestions were made by Sally I. Lapey, Harry McAllister, A. Marzels, and Jacob Mincer. My thanks are also due the Directors' reading committee, which was composed of Wallace J. Campbell, Harold Halcrow, and Lloyd G. Reynolds.

I am indebted to Carl P. Blackwell of the U.S. Department of Commerce for supplying unpublished data underlying the Commerce trade indexes and to Alexander D. Angelidis of the U.S. Department of Agriculture, Foreign Agricultural Service, for information on the Agriculture Department's export and import indexes.

Calculation of the many detailed annual and quarterly indexes would have been impossible without the help of the National Bureau's IBM unit under Martha Jones. The charts represent H. Irving Forman's customary craftsmanship. Joan Tron, as editor, patiently excised unnecessary detail and improved the clarity and style of the presentation.

The greatest debt is to my research assistants. Chief among these was Eleanor Silverman, whose calm efficiency and intelligence benefited every aspect of the study from the collection of the original data to the preparation of the manuscript. Amy Ferrara Hoagland also had an important share in several phases of the study. Many other assistants aided in the collection of the basic trade data and other aspects of the study, particularly Arlene Holen, Robert Kinsey, Anne Novick, Chandra Thakur, Joseph Viladas, and Lucille Wu. Doris Preston was responsible for the checking of the final manuscript.

PRICE AND QUANTITY TRENDS IN THE
FOREIGN TRADE OF THE
UNITED STATES

Introduction

THIS study grew out of the National Bureau's interest in two related aspects of the international economic relations of the United States: "long-term movements of men, commodities, services, and securities . . . examined against the background of secular movements in the domestic economy . . ."; and the cyclical behavior of American international trade and finance.

In both trend and cycle studies, a major obstacle to the analysis of changes in commodity trade has been the lack of data needed in order to separate price from quantity changes over a long period. This investigation was undertaken mainly to provide comprehensive and detailed price and quantity indexes useful for long-term and for short-term analysis.

Data previously published consisted chiefly of official U.S. Department of Commerce indexes for total exports and imports and five major economic classes. These indexes provided annual figures for 1913 and 1919-28, and quarterly or monthly figures for later years. They are fairly satisfactory,² except that export coverage has recently become somewhat inadequate among finished manufactures. We accepted these Commerce indexes for the period after 1923, and have concentrated our attention on the earlier years for which the data were less reliable.³

The only existing indexes of total trade for 1879 to 1913 are those computed by Theodore J. Kreps.⁴ These measured total exports and imports

² Arthur F. Burns, *The Cumulation of Economic Knowledge*, National Bureau of Economic Research, 28th Annual Report, May 1948, p. 22.

³ The export and import price indexes of the Department of Commerce are appraised by the Price Statistics Review Committee of the National Bureau in *The Price Statistics of the Federal Government*, New York, National Bureau of Economic Research, 1961, Appendix A, pp. 79-86.

⁴ For use in business cycle analysis, some provision must be made for filling the gap between the end of the NBER quarterly data in 1923 and the beginning of the Commerce quarterly data in 1929. A set of monthly export indexes constructed by Dudley J. Cowden in *Measures of Exports of the United States*, New York, 1931, can be used as an interpolator for the annual Commerce series for the 1924-28 period. On the import side, however, only a very inadequate American Tariff League index is available for intervals shorter than a year. We therefore produced a quarterly interpolating series for the five major economic classes of imports. The calculation of these is explained in Appendix D.

⁵ "Import and Export Prices in the United States and the Terms of International Trade, 1880-1914," *Quarterly Journal of Economics*, August 1926.

A very crude pair of export and import price indexes was constructed from wholesale price data for 1866-78 by Frank D. Graham in "International Trade Under Depreciated Paper. The United States, 1862-79," *Quarterly Journal of Economics*, February 1922. These were extended back to 1860 by Matthew Simon in "The United States Balance of Payments, 1861-1900," in *Trends in the American Economy in the Nineteenth Century*, Studies in Income and Wealth 24, Princeton University Press for NBER, 1960. Douglass C. North presents new export and import price indexes for the U.S. in the period before 1860 in *The Economic Growth of the United States, 1790-1860*, Englewood Cliffs, N.J., 1961.

only, with no breakdown by commodity group. They were heavily overweighted with primary, as against manufactured, products, and were available only annually for years ending June 30.

Our new indexes are intended to give a more detailed and a more accurate picture of the period covered by Kreps and the early estimates of the Department of Commerce. The requirement that the data be useful for business cycle analysis necessitated the computation of quarterly indexes. Since quarterly data on imports for consumption were not published, we followed the somewhat asymmetrical procedure of using general imports (rather than imports for consumption) in combination with exports of domestic products.

Because we accepted the Commerce figures for the later period, no important alterations were made in applying the Commerce classification system to earlier years, even where changes seemed desirable to make the categories more homogeneous or economically significant.

We have, however, subdivided the Department of Commerce economic classes considerably and constructed a number of combinations of the detailed indexes. For example, Export Class 207 (foodstuffs, excluding tobacco and products) matches the two Department of Commerce food classes (crude and manufactured), while Export Class 208 (foodstuffs, including tobacco and products) was constructed to fit more closely into the United Nations classification¹ or that used by the United Kingdom. Some of the minor classes of Appendix C fit fairly well into the industrial classification of domestic output, although not as well, of course, as if they had been specifically designed for that purpose.

Commodity prices and volumes describe a good deal, but by no means all, of what one might wish to know in order to analyze the changing size and composition of American trade. The American data, unlike those of many other countries, exclude ocean freight costs on both sides of the account, thus removing the need for an *f o b = c i f* adjustment to make export and import data comparable. This characteristic of the data leaves the development of transportation costs outside the area of this study, although these costs are of great importance. A forthcoming study by Douglass C. North² should make possible a combination of commodity prices and transportation costs for much of the period covered here.

Another missing variable, on both the export and import sides, is the tariff. There is no information readily available on tariff rates applicable

¹ United Nations, *Standard International Trade Classification*, Statistical Papers, Series M, No. 10, 2nd Edition, New York, 1931.

² Summarized in "Ocean Freight Rates and Economic Development, 1750-1913," *Journal of Economic History*, December 1938.

to exports; some kind of composite of the tariffs of importing countries would be the appropriate rate. For American imports there is a tariff index with U.S. wholesale price index weights covering the period 1907 through 1946.⁷ There are also data, covering a much longer period, on the ratio of total tariffs collected to total dutiable imports, or total imports. These, as tariff indexes, have the obvious defect that the level of the tariff rate on a commodity influences the weight of the commodity in the index. A sufficiently high tariff could conceivably remove itself from the index by eliminating the import. Nevertheless, these ratios, which were used as tariff indexes by Humphrey⁸ for example, were appraised by Lerdaу as being "far less suspect than it would appear on theoretical grounds."⁹ Neither of these indexes is altogether satisfactory, but Lerdaу found that his had some net explanatory value in a correlation analysis in which the ratio of imports to gross national product was the dependent variable. Either of these indexes could be combined with our price indexes to produce a crude estimate of changes in the prices actually facing American purchasers of foreign goods.

A number of adjustments to the official series on the total value of U.S. exports and imports have been suggested, both in official customs reports and by independent scholars. We have incorporated into our indexes only those two adjustments which proved allocable by commodity, but it would be fairly simple to make other adjustments in the totals.

For example, exports by land, omitted from U.S. customs data before 1893, could be added. Matthew Simon, using Canadian import data,¹⁰ made such an adjustment in the aggregate figures, but our attempt to break these down by commodity groups was frustrated by difficulties in matching Canadian and U.S. commodity classifications. For a number of products, exports reported by the U.S. were greater than the reported Canadian imports despite the presumed exclusion of exports by land from the U.S. data.

Simon also adjusted for a discontinuity in the prescribed method of valuation of imported commodities: he increased the 1884-91 values by 5 per cent to add certain inland freight and other costs. This followed a suggestion made by the Chief of the Bureau of Statistics.¹¹ We were not able to find any basis for applying this adjustment to individual com-

INTRODUCTION

modities. Since it could have varied a great deal from one commodity to another, we did not take it into account at all.

We have tampered with the official value series in only two ways. The first was a *correction* for the overvaluation of imports from Brazil in the early 1890's which resulted from the depreciation of the paper milreis. The error was conspicuous and was concentrated in two important commodities, coffee and rubber. More realistic values were estimated by using official quantity data (which were not affected) in combination with outside data on rubber and coffee prices. A description of the adjustment is given in Appendix C.

Official values were further adjusted for changes in the U.S. customs area which took place in 1900. Here again the adjustment, which is described in Appendix F, rested on fairly reliable data and was concentrated in two commodities, exports of green coffee and imports of sugar.

Many fundamental questions about the meaning or validity of long-term comparisons of price levels and terms of trade have been ignored here, as in most empirical discussion of these problems. Except in Chapter 3, where several types of index numbers are compared, we have generally used the Fisher 'ideal' indexes to represent "price" and "quantity" as if these terms were unambiguous and independent of the particular weights from which they were computed. It is also assumed that the shift after 1923 from one type of index to another, and the shifts from one base (or weighting pattern) to another before that date, do not by themselves make comparisons meaningless.

The first two chapters survey the outstanding changes in the foreign trade of the United States over the last eighty years. The remaining chapters deal primarily with the construction of the NBER indexes, appraisals of their quality, and an interpretation of the relations among the several types of indexes.

Chapter 1 sets forth the findings on U.S. export and import prices, and their relation to domestic prices and to the export prices of other countries. It describes the evidence relating to the terms of trade of the United States and the terms of trade of primary and agricultural products. Relations between price and productivity changes are also discussed.

Chapter 2 is concerned mainly with quantity trends in relation to domestic output and to the trade of foreign countries. Possible price-quantity reactions are also explored.

The method by which the NBER indexes were constructed is explained in Chapter 3, and comparisons of Paasche and Laspeyres indexes are used as evidence of the connections between price and quantity changes.

INTRODUCTION

Characteristics of the basic data on export and import quantities and prices are discussed in Chapter 4, with particular reference to the problems involved in using unit value data as prices.

Chapter 5 contains an account of the use of sampling ideas in the construction and appraisal of index numbers and describes estimates of sampling error in the NBER indexes.

Finally the new price and quantity indexes are compared, in Chapter 6, with those of Kreps and the Department of Commerce, as well as with indexes of the Department of Agriculture and the Bureau of the Census.

CHAPTER 1

Trends in Prices and Terms of Trade

Summary View of U.S. Export and Import Prices and Terms of Trade

The history of the international trade of the United States during the last eighty years is divided into three segments by the two world wars. The 'prewar period' covers the thirty-five years before World War I. For these years the NBER indexes presented here provide an extensive set of new data. The interwar period covers the twenty-one years from 1919 to 1939. For this segment, we use new NBER data only through 1923, Commerce Department estimates and other series are used for later years. The postwar period, from 1946 through 1960, is discussed entirely in terms of data compiled originally by others.

In any analysis of long-term trends in this eighty-year period, the treatment of the 1930's poses a difficult problem. For many series, such as the terms of trade and import prices shown in Chart 1, the levels of the 1930's were unprecedented and seem unlikely to recur. Yet because these years stand nearer to the end than to the beginning of our period, they exert a strong influence on estimated trends. (In the terms-of-trade series, for example, they impart a considerable upward slant to a fitted trend.) For this reason, we have frequently omitted consideration of the interwar period and compared the 1950's directly with the prewar years.

This period should not, however, be ignored completely. Much recent discussion of the terms of trade, ratios of trade to output, and price-quantity relations has been colored by, and can only be understood in terms of, the events of the depression years.

EXPORT AND IMPORT PRICES

In the prewar years, a period of declining prices before 1898 was followed by rising prices up to World War I (Chart 1). No substantial trend for the period as a whole can be discerned, although import prices in 1909-13 were below the level of thirty years earlier. At the end of World War I, and for two years thereafter, prices were far higher than before—in 1920, almost twice the prewar peak for imports and more than twice for exports. After 1920, however, the interwar period was characterized by devastating price declines and comparatively weak recoveries. In the single year 1921, and again in 1931-32, export and import prices fell a distance equal, or almost equal, to the whole range of their prewar fluctuations. The fall

TRENDS IN PRICES AND TERMS OF TRADE

CHART 1

U.S. Export and Import Prices and Terms of Trade

Source: Appendix Tables A-1, A-3, and H-1.

brought import prices in twelve years from the post-World War I peaks to a level substantially below that of the trough in the late 1890's. Even a sharp recovery after 1933 did not carry them much above the prewar low. For exports, the decline in prices was slightly less severe, but they too fell below the prewar average. The recovery in the late 1930's brought export prices back to the level of the higher prewar years.

The end of World War II again found prices far above the interwar levels. In contrast to the earlier experience, it was import prices that had risen the most. In even stronger contrast, the postwar rise was followed, not by a collapse, but by further price increases. These tapered off somewhat or, in the case of imports, were mildly reversed after 1951. The postwar peaks barely surpassed those of the early 1920's but were far above any of the longer lasting prewar or interwar price levels.

A distinct shift took place also in the relative volatility of export and import prices. Before World War I, export prices underwent sharper fluctuations than imports, reaching a lower trough in the 1890's particularly. After 1918 prices of imports suffered the more violent changes, and continued to do so into the postwar period.

U S TERMS OF TRADE

Export and import prices determine the net barter terms of trade which have been the subject of much acrimonious discussion in the postwar period (the controversy is discussed in a later section of this chapter). Despite the suspicion, current since the late 1930's, that the developed countries have experienced very large long-term gains in their terms of trade, little trend can be discerned in the U S figures. This is illustrated by the fact that the 1949-58 terms of trade were close to most prewar levels. The average for all the postwar years, however, was slightly higher, and the 1959-60 indexes matched the highest prewar figures. But all except the first few postwar figures are far below the heights reached in the interwar period.

Much more definite changes have taken place in the pattern of short-term movements. The prewar fluctuations in the terms of trade roughly followed those of prices. After rising at first, they fell to a low point in the 1890's (earlier than prices), and then rose again. During World War I, the terms-of-trade index increased sharply, as did the price level, but there the resemblance ended. During both the interwar period and the postwar years, the movement in the terms of trade was closer to being inverse than conforming to the price level, particularly during sharp price fluctuations.

TRENDS IN PRICES AND TERMS OF TRADE

This switch in behavior is a reflection of the fact, mentioned above, that export prices fluctuated more violently than import prices before World War I, and import prices more sharply thereafter.

The greatest fluctuations in the terms-of-trade index took place during the interwar and early postwar period. In several instances, the index covered the whole span of prewar changes within two or three years.

The interwar period was the most "favorable" to the United States in the eighty years considered here. In the mid-1930's, the terms of trade briefly reached 40 per cent above the 1913 level and more than 50 per cent above the trough levels of the 1890's, but these levels were never reached again after World War II.

During World War II and for several years after, the terms of trade shifted sharply against the United States, falling briefly during the Korean War to the level of the 1890's before rising moderately again.

COMPARISON OF NBER AND KREPS INDEXES

The only previously available series on prewar United States foreign trade prices were those published by Kreps in 1926.¹ Our indexes differ substantially from his, as can be seen in Table 1.²

For export prices, the two series agree in showing virtually no change between 1880 and 1913. However, the Kreps index shows a rise more than double that of the NBER index between the 1880's as a whole and 1913. In addition, the Kreps index undergoes sharper fluctuations, particularly before 1900, and falls more steeply to the trough in the late 1890's.

TABLE 1
COMPARISON OF KREPS AND NBER INDEXES OF U.S. EXPORT AND
IMPORT PRICES AND TERMS OF TRADE
(1913 = 100)

	Fiscal Year 1880		Average of Fiscal Years 1880-89	
	Kreps	NBER	Kreps	NBER
Exports	100.0	99.7	91.3	95.9
Imports	131.7	109.3	108.9	98.1
Terms of Trade (E/I)	75.9	91.2	84.2	98.0

SOURCE: Appendix Tables G-1 and H-2.

¹ Theodore J. Kreps, "Export and Import Prices in the United States and the Terms of International Trade, 1880-1914," *Quarterly Journal of Economics*, August 1926, p. 708.

² A more detailed comparison of the two sets of indexes and some explanations of the discrepancies between them appear in Chapter 6.

TRENDS IN PRICES AND TERMS OF TRADE

The import price series differ even more radically, the Kreps index exhibits not only wider fluctuations but a much stronger downward trend. It declines by 24 per cent between 1880 and 1913, as compared with 8 per cent for the NBER series, and by 8 per cent from 1880-89 to 1913, when our series actually rises slightly.

These differences in opposite directions for export and import prices make the two terms-of-trade indexes diverge even more widely. Kreps shows a 32 per cent improvement in U.S. terms of trade from 1880 to 1913 and 19 per cent from the decade of the 1880's to 1913. The corresponding increases in the NBER index were 9 per cent and 2 per cent.

If we stretch this comparison, perhaps recklessly, to the 1950's, the Kreps indexes, linked to those of the Commerce Department suggest an improvement in the U.S. net barter terms of trade of about 15 per cent since the 1880's. Our indexes indicate virtually no change.

International Comparisons of Terms of Trade

TERMS OF TRADE OF INDUSTRIAL COUNTRIES

The NBER export and import price indexes for the United States provide new evidence in the controversy over long-run trends in the terms of trade. There are really two questions at issue, and an answer to one does not, as is sometimes assumed, necessarily provide a key to the other.

(1) Have long run trends in the terms of trade been favorable to developed or industrialized countries¹ and by inference, unfavorable to underdeveloped countries?

(2) Have the terms of trade moved in favor of manufactured goods as compared to primary products? We attempt to develop some evidence on the first question here, and on the second in the next section, but much of the evidence is applicable to both questions.

There is a widely-held belief that the terms of trade have moved in favor of industrialized countries in the long run.⁴ It is, therefore, of some interest to review the existing data and to observe the effect of introducing the new U.S. indexes.

One set of comparisons was made by K. Martin and F. G. Thackeray

¹ The terms are not, of course, interchangeable, an agricultural country could well be developed. Most of the comparisons have referred to countries which were both developed and industrialized.

⁴ See, for example, United Nations *Relative Prices of Exports and Imports of Under-Developed Countries*, (New York, 1949), pp. 21-23, where U.K. data are offered as evidence.

in 1948.⁵ Of the three industrial nations for which they presented prewar data, Germany showed a decline in the terms of trade and the U.S. and U.K. a rise. The U.S. figures, however, were derived from Kreps' data. A substitution of the NBER indexes would put the U.S. in an intermediate position and shift the results toward a finding that no substantial change had taken place in the terms of trade of industrial countries between 1879 and 1913.⁶

For the interwar period, Martin and Thackeray show improved terms of trade for the U.S., the U.K., and Germany, and a deterioration only for Japan. But the final year of their study was 1938, almost the peak for terms of trade of industrialized countries. Extension of these data to 1960 would wipe out all the gains since 1920 for the U.S. and the U.K. and all since 1925 (the first year shown) for Germany. The U.K. terms of trade would remain, however, considerably above the 1913 level.⁷

Kindleberger's data showed that the improvement in U.K. terms of trade, from which the deterioration in underdeveloped countries' terms of trade had been inferred, was not characteristic of the rest of industrial Europe. For both 1870-1913 and 1870-1952, U.K. terms of trade improved while those of industrial Europe as a whole (including the U.K.) declined.⁸ The implication is that there was a considerably larger decline in the terms of trade of continental industrial Europe (CIE).⁹

A positive relationship between stage of development and terms of trade does, however, emerge from other features of Kindleberger's data. The more developed countries within industrial Europe, such as Belgium, Sweden, and Switzerland, improved their long-run terms of trade by comparison with the less developed members of that group, France and Italy.

Kindleberger further found that, in its trade with industrial Europe, the area he calls "all other countries"¹⁰ suffered a major deterioration in terms of trade, by as much as one-quarter between 1872 and 1952. This was the most unfavorable experience among all the areas he distinguished.¹¹

⁵ *Bulletin of the Oxford Institute of Statistics*, Vol. 10, No. 11, November 1948, pp. 373-398.

⁶ Martin and Thackeray classify the United States as a primary producer before 1900 (*Ibid.*, p. 374). It is true that the United States was at that time an exporter primarily of agricultural products, but it was already a developed, industrial country in terms of the distribution of the labor force or of income originating by sector.

⁷ These statements are based on our data for the U.S. and on indexes for European countries from Charles P. Kindleberger, *The Terms of Trade: A European Case Study*, New York, 1956.

⁸ *Ibid.*, pp. 53-57.

⁹ Industrial Europe excluding the United Kingdom.

¹⁰ Mostly made up of underdeveloped countries but also including Japan.

TRENDS IN PRICES AND TERMS OF TRADE

COMPARISONS OF TERMS OF TRADE U S AND OTHER COUNTRIES

Two features stand out in the comparison of U.S. terms of trade with those of the U.K. and with our crude estimates for "Continental Industrial Europe" (CIE) in Chart 2. One is that British terms of trade increased considerably relative to the other two over the period for which they can be compared. The other is that the behaviour of U.S. terms of trade,

CHART 2
Terms of Trade of U.S., U.K., and Industrial Europe

Source: Appendix Tables H 1, H 3, and H-4

independent of or even inverse to that of Europe before 1920, became quite similar after that date.

Over the whole time span, as was pointed out earlier in this chapter, U.S. terms of trade did not change substantially. Those of industrial Europe rose somewhat, but most or all of this increase disappears if we make a very crude adjustment to remove the U.K. The reason for this effect is clear (see lower half of Chart 2): British terms of trade rose substantially from 1879 to the end of World War II. From the 1880's to the 1950's they gained by over 37 per cent according to Schlote's index for the period up to 1913—slightly less if Imlah's data are used.¹² The largest gains in the U.K. index, relative to CIE and the U.S., came in the prewar period and during World War I. The end of the war found U.K. terms of trade 20 per cent higher than in 1913, and those of CIE, 20 per cent lower.¹³

In the short-run behavior of U.S. terms of trade, a sharp shift may be noted. In the prewar years, as was pointed out earlier in this chapter, they moved with prices and were roughly inverse to the terms of trade of the U.K. and CIE. They reached a peak in the 1880's (but later than the trough in the other series) and a trough in the 1890's (earlier than the peak in the others). After World War I, when U.S. terms of trade became inverse to price changes, they conformed well to both British and CIE terms of trade. It might be said that the trade pattern matured, developing from one that is characteristic of a primary goods exporter to one characteristic of a nation exporting manufactured products.

The terms of trade may be resolved into export and import price components which are shown in Chart 3. After 1913, the rise in U.K. trade terms in relation to those of the U.S. is seen to be mainly on the export side, where American prices fell by 20 per cent relative to British prices. For the prewar period, there are two explanations for the behavior of U.K. terms of trade. In Schlote's estimates, most of the change relative to the U.S. (and to CIE as well) took place on the export side of the account; U.S. export prices fell by roughly 15 per cent relative to British prices between the 1880's and 1913. Imlah, on the other hand, finds U.K. export prices keeping pace with those of the U.S. over the same periods, and rising only slightly by comparison with CIE.

¹² Werner Schlote, *British Overseas Trade from 1700 to the 1880's*, Oxford, 1952, and Albert H. Imlah, *Economic Elements in the Pax Britannica*, Cambridge, Mass., 1958.

¹³ There are some peculiarities in the CIE index in the first few years after World War I. Germany does not appear to be included in 1920 and then apparently enters at very low export-price and terms-of-trade levels in 1921 and 1922. See Kindleberger, *Terms of Trade*, pp. 13 and 23.

TRENDS IN PRICES AND TERMS OF TRADE

CHART 3

Ratio of U.S. Export and Import Prices to Those of the U.K.
and Continental Industrial Europe
(1913 ratio = 100)

Source: Appendix Tables H-5 through H-8.

TRENDS IN PRICES AND TERMS OF TRADE

For imports, Schlote's estimates show the U.K.'s prices moving with those of both the U.S. and CIE, while Imlah's data show them falling relative to both by about 6 per cent. Both authors agree, however, in finding considerable improvement in U.K. terms of trade—Schlote, a somewhat greater one.

If U.S. prices are compared with those of CIE, they show a fall in both exports and imports with, perhaps, a slight relative decline in U.S. terms of trade.

To summarize, among the three industrialized areas compared, only one—the U.K.—showed evidence of substantial gains in its terms of trade. Neither our new indexes for the U.S. nor Kindleberger's data for continental industrial Europe confirm the belief that industrial countries as a whole have enjoyed large improvements in their trade terms since the 1870's or 1880's. The experience of the U.K. cannot be taken as typical of developed countries.¹⁴

Prices of Primary and Manufactured Products

OTHER STUDIES

The conviction has been widespread in the last twenty years that, compared to prices of manufactures, primary product prices inexorably decline in the long run and that they have, in fact, declined by a substantial amount since the 1870's or 1880's. This idea has become widely accepted despite its contradiction of the classical belief, dating back at least to Robert Torrens, that "the exchange value of manufactured articles, compared with the products of agriculture and of mines, have, as population and industry advance, a certain and decided tendency to fall."¹⁵

It was noted, during the British debate over the terms of trade in the 1920's, that the operation of this "law" seemed to have been suspended at

¹⁴ Robert E. Baldwin in "Secular Movements in the Terms of Trade," *American Economic Review*, No. 2, May 1955 (Papers and Proceedings), suggests that differences in the type of index number used are sources of bias or of divergent interpretations. During the period covered by the NBER indexes, however, the U.S. terms of trade calculated from Laspeyres indexes diverged greatly from those calculated from Paasche indexes only during World War I. The difference between them widened from 2.5 in 1879 to 4.7 in 1923 (1913 as 100).

¹⁵ John Stuart Mill, *Principles of Political Economy*, New York, 1909, Vol. II, Book IV, Chapter 2, p. 282.

The history of the debate over this proposition is reviewed extensively by Walt W. Rostow in *The Process of Economic Growth*, New York, 1952, pp. 173 and 182-192, and by J. M. Letiche, "The Relevance of Classical and Contemporary Theories of Growth to Economic Development," *American Economic Review*, May 1959.

various times, such as during the 1890s. But the fundamental tendency toward declining relative prices of manufactures was challenged only to the point of suggesting that agricultural productivity might possibly keep up with that of manufactures indefinitely. The participants in the argument generally assumed that relative productivity trends were the key to price trends.

It was Folke Hilgerdt who first turned the classical proposition upside down. He argued that, in the sixty years before 1938, primary product prices had fallen relative to prices of manufactures and that "the general trend of the relative movements . . . of the prices of these two classes of goods can scarcely be doubted."¹⁶ The evidence for this contention consisted of League of Nations indexes for primary product and manufactured goods prices.¹⁷ These, for the period before 1929 when most of the apparent fall in the relative prices of primary goods took place, rested entirely on two indexes: one, a combination of Schlote's indexes for British exports and imports of manufactures, the other, for primary products, the Sauerbeck wholesale price index.¹⁸

The theme of declining relative prices for primary products was taken up after the war in a series of United Nations documents.¹⁹ None of these were primarily concerned with the prewar period; they treated the long-term deterioration in primary product prices as an established fact, relying on Hilgerdt and Schlote.

The view that primary producers have suffered from deteriorating terms of trade has been challenged, on both the facts and their interpretation. We shall not deal with the questions of interpretation except in discussing U.S. productivity trends in the next section of this chapter. Haberler, Viner, and Baldwin have pointed to the likelihood that price indexes of manufactures are biased upward because of the neglect of

¹⁶ League of Nations, *Industrialization and Foreign Trade*, 1945, p. 16. It is ironic that, despite the classical tradition on this question, the only opposing view that Hilgerdt mentioned was that of the protectionist theorist, Manólesco.

¹⁷ *Ibid.*, p. 157.

¹⁸ *Ibid.*, p. 154. The Schlote indexes appear in *British Overseas Trade*.

¹⁹ For example, *Relative Prices of Exports and Imports of Underdeveloped Countries*, 1949, pp. 21-24, and several publications of the Economic Commission for Latin America, particularly *The Economic Development of Latin America and its Principal Problems* [by Raul Prebisch] 1950, pp. 8-10.

²⁰ Jacob Viner, *International Trade and Economic Development*, Glencoe, Ill., 1952, p. 143; Robert E. Baldwin, "Secular Movements in the Terms of Trade," *American Economic Review*, No. 2, May 1955 (Papers and Proceedings), Gottfried Haberler, "Introduction," in *Problems in International Economics* pp. 73-81, and *International Trade and Economic Development*, Cairo, National Bank of Egypt, Fiftieth Anniversary Commemoration Lectures, 1959.

quality changes and underrepresentation of new commodities.²¹ The same authors have made the additional point that one cannot, by simply inverting a country's terms of trade, derive the terms of trade for its partners. When exports are reported in trade statistics on an f.o.b. basis (excluding, among other things, freight costs) and imports are reported c.i.f. (including freight costs), as is the case with the U.K., it is possible for the terms of trade, measured in home prices, to improve for both countries simultaneously. The necessary condition for such an outcome is a fall in shipping costs relative to prices; this does seem to have occurred during the nineteenth century.²¹

We have already mentioned the likelihood that U.K. export prices and terms of trade, particularly in Schlote's data, were biased upward as a measure of the experience of industrial nations generally. Kindleberger²² found no clear trend in the terms of trade of primary products vs. manufactures and suggested that the large country and product dispersion in the price indexes made the question almost meaningless.

A recent study by Theodore Morgan,²³ which examined prices of manufactured and agricultural products in seven countries, concluded that there was great diversity of experience but no evidence of declining relative prices for agricultural commodities.

From a review of Kindleberger's data, combined with U.S. price indexes for the period since 1913, Sarah S. Montgomery found signs of improvement rather than deterioration in world terms of trade for primary products.²⁴ This was especially the case when they were measured in terms of prices within primary producing countries. The decline in freight rates relative to commodity prices tended to make the price relationships in the industrial countries (where imports were valued c.i.f.) appear less favorable to the primary producers than they really were. In other words, at least part of the decline in relative prices of primary product imports represented a fall in transport costs rather than a decline in the return to the primary producer.

²¹ See P. T. Ellsworth, "The Terms of Trade Between Primary Producing and Industrial Countries," *Inter-American Economic Affairs*, Vol. X, Summer 1956. Data on freight rates appear in Douglass North, "Ocean Freight Rates and Economic Development," *Journal of Economic History*, Dec. 1958, and in Sarah S. Montgomery, "The Terms of Trade of Primary Products and Manufactured Goods in International Trade, 1870-1952," unpublished Ph. D. dissertation, University of Wisconsin, 1960.

TRENDS IN PRICES AND TERMS OF TRADE

EVIDENCE FROM NBER DATA

The NBER export and import price indexes may be viewed as a new set of observations bearing on the relative prices of manufactured and agricultural or primary products entering into international trade. Four measures of this relationship are described in Chart 4 and Appendix Table H 9.

The clearest trends relate to U.S. agricultural exports. Between the 1880s and the 1900s the purchasing power of manufactured imports (foreign manufactures) over American exports of farm products fell by 20 per cent or more—mostly between the middle 1890s and the 1920s. Since then there has been no clear secular trend. Within U.S. exports the change has been more violent—the price of manufactured products declined by almost half in comparison with agricultural products. Here too the largest drop came after 1894; another large fall during World War II was only partially reversed afterward.

Although the purchasing power of U.S. manufactured exports over agricultural imports rose during the 1930s to heights 60 to 60 per cent above 1879 or 1913, it has since declined to the point where no definite trend can be identified. The 1900s as a whole show some deterioration compared with the 1880s and 1913—in fact with the whole prewar period. But the levels of the ratio for 1879-81, 1913, and 1908-60 are almost identical and the verdict must be—probably no change, possibly a slight decline.

Only within imports do manufactured goods prices exhibit a relative gain. Manufactures imported into the U.S. increased in price by about 20 per cent between the 1880s and the 1900s compared with foreign agricultural products. The gain took the form of a substantial increase before World War I followed by a great jump during the war and in the 1930s and then a retreat to the level of the 1920s.

Two price relationships are implied but not stated in these indexes. One was a great decline in the ratio of export to import prices of manufactured goods (from 127 in the 1880s to 78 in the 1900s)²²; the other was a large increase in the ratio of export to import prices among agricultural products—from 79 in the 1880-89 decade to 125 in 1900-59.

Not all primary products are agricultural and the proportion which is has undoubtedly fallen over the last eighty years within both exports and imports. For the years through 1923, in addition to the index for finished manufactures we have an NBER index for "all commodities other than manufactures"—a broad definition of primary products. But for the later

²² From 1901 to 1909, however, there was a steady rise, peaking only in 1904.

TRENDS IN PRICES AND TERMS OF TRADE

(1913 ratio = 100)

Source: Appendix Table H-9.

years, there is no similar index available. The direction of change in the ratio of manufactured to primary product prices can be calculated, however, by comparing manufactured to total export and import prices; the relation to total primary product prices would always be in the same direction, but stronger.

This comparison is made, using only prewar and postwar data, in Table 2. On the export side, the relation with agriculture is confirmed. U.S. export prices for manufactures fell by more than one quarter with

change. By 1959-60, however, all four had fallen slightly below the level of the 1880's. Manufactured imports rose in price relative to four groups and fell relative to the other four; the rises were generally stronger than the falls.

Before 1913, relative prices of manufactures clearly declined. U.S. exports of primary products rose in price compared to exports and imports of manufactures in all eight comparisons and U.S. imports of manufactures fell in price in five out of eight. Since 1913, manufactured imports have risen in price relative to seven out of eight primary product classes. Manufactured exports have gained compared to four primary classes and lost in comparison with four others.

What conclusion can now be reached regarding the terms of trade between primary and manufactured commodities? For the period before 1913, the weight of evidence indicates declining terms of trade for manufactured goods. This is particularly clear for American manufactures but also appears true for foreign manufactures. Over the whole eighty years the picture is not quite as clear. U.S. exports of manufactures declined in price relative to total primary imports and exports and to agricultural exports; compared with agricultural import prices, they changed very little, possibly falling slightly. Imported manufactures fell in price relative to U.S. agricultural exports but rose compared with total primary product imports and exports and agricultural imports.

In summary, comparisons with exports of U.S. manufactures strongly contradict the belief in declining relative primary product prices; comparisons with manufactures imported into the U.S. mildly confirm it. On the whole, there seem to be more instances of primary products relatively gaining in price than losing. The scatter around the relationships among totals is large, and supports Kindleberger's view that the primary vs. manufactured product distinction is not a particularly useful one for the analysis of changes in terms of trade.

We have used the terms "favorable change" or "favorable direction" frequently as a synonym for a rise in prices. From the cases mentioned, however, it should be clear that rising prices were often not really favorable to the producers concerned. Some instances clearly represented producers who were losing their world markets, perhaps because their productivity was lagging behind that of industries or countries with "unfavorable" changes in prices or terms of trade. Some evidence on the effect of productivity movements is discussed in the next section of this chapter, and Chapter 2 deals further with the interrelationships of price and quantity change.

Price and Productivity Changes

Great divergences among price trends for different classes of commodities are among the central facts of economic history. Upon the interpretation of these trends rest many of our explanations for the growth and decline of nations, classes, and industries, and for the enrichment of one class or nation and the impoverishment of another.

One such interpretation (often referred to as the Singer-Prebisch thesis)²⁶ is based on the belief, discussed earlier, that the terms of trade of primary products vis-à-vis manufactured goods have deteriorated over the long run,²⁷ and that these trends have led to a widening of the gap in real income between primary and manufactured goods producers.²⁸ Crucial to this conclusion is the conviction that productivity changes have not been responsible for the deterioration in primary products' terms of trade—that in fact, they have tended in the opposite direction.

A great deal of data on productivity by sectors in many countries would be required to investigate thoroughly the influence of productivity changes on international price relationships. We have made no attempt to collect such data, and much of the necessary information is probably not available. But the development and refinement of productivity measures for various sectors of the American economy offer opportunities for analysis of price changes within American exports. We have, as an experiment, examined the long-term decline in the prices of U.S. exports of manufactures relative to those of U.S. exports of agricultural products.²⁹ A comparison of available productivity data with the list of export indexes in Appendixes A to C would probably suggest other candidates for investigation.

²⁶ See, for example, H. W. Singer, "The Distribution of Gains Between Investing and Borrowing Countries," *American Economic Review*, May 1950, pp. 477-478, and *The Economic Development of Latin America*.

²⁷ An alternative version of the thesis emphasizes the terms of trade of underdeveloped countries vis-à-vis the more advanced countries, which is not necessarily the same question, as Kindleberger and Singer himself have pointed out. Singer later stated a preference for the second version, "my original emphasis was too much on primary commodities and their characteristics and not enough on underdeveloped countries and their characteristics." (Comment on Kindleberger's "Terms of Trade and Economic Development," p. 88).

²⁸ Just as it is crucial to arguments for agricultural price parity programs within the industrial countries which attempt to keep parity ratios constant over long periods of time.

²⁹ Our findings regarding price changes within U.S. exports would not necessarily apply, of course, to changes between export and import prices or within imports. But Singer, in the comment on Kindleberger's paper quoted above, hints they are related: "I gladly accept this shift in emphasis (from primary products to underdeveloped countries) even though it leaves the chronic troubles of the primary producers within the industrial countries to be explained" (*ibid*).

TRENDS IN PRICES AND TERMS OF TRADE

As can be inferred from the preceding section of this chapter, the net barter terms of trade for agricultural and manufactured exports²⁰ showed very different trends (Chart 5). The purchasing power of agricultural exports rose by about 50 per cent between the 1880s and the interwar period, fluctuated around the interwar level during the early 1950s, and then declined to roughly 30 per cent above the 1880s level. The purchasing power of manufactured exports over imports, on the other hand, fell by 15 to 20 per cent before World War I, climbed to a peak in 1932, and then declined again to a postwar average below that of 1913. Only in 1959-60 did it regain the 1913 level. K3

It would be wrong, of course, to read into these figures a decline in welfare for the producers of manufactured products (measured in terms of ability to purchase imports). For this we would wish to know, not the purchasing power of a unit of output, which we have measured, but purchasing power per unit of input. This is estimated as the product of the net barter terms-of-trade index and a productivity index. It represents, for each of the two sectors, Viner's "single factorial terms of trade"²¹.

We calculated this measure from the NBER and Commerce export and import prices indexes and Kendrick's indexes of output per manhour and total factor productivity.²² These last take account not only of manhours worked but also of capital employed and, in the case of manufacturing, of changes in the composition of the labor force. 57421

The results of this computation (Chart 5) give a far different impression from that implied by the net barter terms of trade. In terms of inputs, the purchasing power of both agricultural and manufacturing factors of production increased greatly. In the 1950s, it was four to five times the initial level, measured by output per manhour, and three to four times as high, measuring by "total factor productivity." The growth of purchasing

²⁰ We refer here to the ratio of their prices to total import prices or, in other words, their purchasing power over imports in general.

²¹ Jacob Viner, *Studies in the Theory of International Trade*, New York, 1937, pp. 558-559.

²² John W. Kendrick, *Productivity Trends in the United States*, Princeton for NBER, 1961, Appendixes B and D. Many doubtful aspects of this computation spring to mind immediately. For one thing, manufacturing and agriculture, as industries, do not coincide with what we call manufactured and agricultural exports. The main culprit in this in comparability is the class of manufactured foodstuffs, most of which we class as agricultural even though part of their value has been added in manufacturing and they are included in the manufactured products productivity index. Their price behavior, however, was similar to that of crude foods.

Weighting is another problem. The appropriate productivity indexes for such a computation would have export rather than domestic weights. There are also differences in valuation, a good part of the value of many exports, as reported in our data, was added by the transportation industry as well as by others which intervene between the producer and the exporter.

TRENDS IN PRICES AND TERMS OF TRADE

power over imports by manufacturing factors of production was quite similar to that for agricultural factors, although the latter retained some advantage

These price and productivity relations can be examined from a slightly different viewpoint. We may ask how much of the very great decline in price of manufactured exports relative to agricultural exports can be accounted for by productivity differentials?

Chart 6 gives the answer to this question. The total relative decline in price of manufactured exports was approximately 50 per cent between the 1880s and the 1950s. Of this, roughly 30 per cent was accounted for by differential productivity movements. The other 20 per cent could be said to be the real gain in purchasing power of the agricultural factors

CHART 6

Relation of Manufactured to Agricultural Prices, Productivity,
and Values per Unit of Input
(1913 ratio = 100)

TRENDS IN PRICES AND TERMS OF TRADE

over the factors used in manufacturing production. If we compare the 1880's with 1913, all of the 25-30 per cent fall in purchasing power of manufactures can be explained by productivity differentials, measured by output per manhour; about two-thirds of it can be explained by using total factor productivity. Most of the unaccounted for long-term decline in the price ratio took place after 1913. This decline might represent the overstatement in agricultural productivity involved when only labor inputs are used, since there has been such a great increase in capital intensity in agriculture. To some extent, the price ratios may reflect the effects of U.S. price support policies in keeping up agricultural prices and terms of trade, or they may be affected by changes in inputs *not covered by the indexes*.

Since the end of World War II, there seems to have been some reversal

CHART 6 (Concluded)

Source: Appendix Tables H-9, H-17, and G-7.

of the long-term trends; manufactured goods prices have been gaining on agricultural export prices. This too is in line with productivity movements; output per manhour has recently been growing more rapidly in agriculture than in manufacturing.

We conclude then—to the extent that one can draw a conclusion from so crude a test—that differences in the rate of increase in productivity between manufacturing and agriculture, particularly before World War I, account for most of the long-run decline in price of manufactured goods relative to agricultural products within U.S. exports.³³

The “ratios of value per unit of input”³⁴ in Chart 6 are informative in another respect. They reveal the severity of the depression of the 1930’s for agriculture much more clearly than do the price ratios. The price ratio between agricultural and manufactured products turned sharply against agriculture after 1929, but it remained considerably more favorable than before 1900. The ratios of value per unit of input, however, were more unfavorable to agricultural factors in the 1930’s than at any other time in the period covered here. They were far worse than in the depths of the depression of the 1890’s, and the short-term swings were far larger than any conceivable estimate of the trend.³⁵

Relation of Foreign Trade Prices to Domestic Prices

For the analysis of shifts in the flow of trade or the balance of payments, one is often interested not so much in absolute changes in export and import prices as in their relation to the domestic price level. In both exports and imports, a single large shift in this relationship occurred more than thirty years ago and has not been reversed.

Before World War I, the ratios of export and import prices to domestic prices³⁶ fluctuated within a narrow range (Chart 7). Both exports and imports exhibited a slight downward trend with respect to domestic

³³ Kendrick found (*ibid.*, Chapter 7) that productivity and price changes were highly correlated within manufacturing—productivity accounting for half or more of the variation in price movements.

³⁴ These ratios are, to some extent, analogous to Viner’s “double factorial terms of trade.”

³⁵ Singer has recently laid heavier stress on the importance of cyclical swings in prices and import earnings as compared to secular trends, in *Problems in International Economics*, pp. 85–86.

³⁶ For domestic prices, the implicit price index underlying GNP was used. Experiments were performed with variants, such as the index underlying the flow of goods to consumers plus gross producer durables, which, by virtue of its omission of services, might be considered more comparable to merchandise trade. The results were so similar to those using GNP that they have not been presented here. Some use is made of a variety of measures of domestic output, however, in Chapter 2.

TRENDS IN PRICES AND TERMS OF TRADE

prices, but at least part of the trend was a result of differences in index number construction.³⁷

The first year of peace found export prices 10 per cent above their pre-war ratio to domestic prices, and import prices 10 per cent below. By the early 1930's, both sets of ratios had fallen about 35 per cent below the 1919 levels. Since then, neither exports nor imports have reached more than 80 per cent of the 1913 price ratio, except briefly, and both have hovered between 70 and 80 per cent through most of the postwar years.

CHART 7
Ratio of Export and Import Prices to Domestic Prices
(1913 ratio = 100)

Source: Appendix Tables H-18 and H-19.

³⁷ The domestic price index is a Paasche price index, derived by dividing what is, in effect, a value index by a Laspeyres quantity index. The foreign trade indexes are Fisher "ideal" index numbers. If, for the period before World War I, we substituted our Paasche price indexes for the Fisher indexes, the downward relative trend in export prices would disappear and the relative decline in import prices would diminish considerably.

Neither export nor import prices have risen far enough to approach even the lowest points in their prewar relations to the domestic price level.

This decline in foreign trade prices could be explained in two ways. It is conceivable that there was considerable divergence between home and export or import prices for individual commodities. Alternatively, commodities that have fallen relatively in price might have greater importance in international trade than in the domestic economy.

The first explanation would be contrary to theoretical expectations regarding competitive markets. Furthermore, our experiments with prewar data (reported in Chapter 4) suggested that export and import prices conform closely to domestic prices where comparisons can be made. On the other hand, these measures covered neither the interwar period, when the largest discrepancies in the indexes appeared, nor the postwar programs for disposal of surplus farm commodities. The latter are likely to have caused some decline in export as compared to domestic agricultural prices.

At least one theoretical consideration might lead us to expect a heavier weight in international trade than in domestic trade for commodities with relatively declining prices. Exports and imports may contain a smaller proportion of what might be called "sheltered" commodities and services—items such as heavy building materials and certain types of personal and business services for which it is difficult to shift to foreign sources of supply when domestic prices rise. In other words, it seems likely that elasticities of substitution, for a single country's production, are higher on the average within international commodity trade than within the domestic economy. As a result, the composition of a country's international trade could be expected to shift more quickly than the composition of its domestic output towards items whose prices are declining relatively. This characteristic by itself would tend to lead to a decline in export and import prices relative to domestic prices.

The ratio of foreign trade prices to the GNP deflator is shown in Chart 8 for manufactured and agricultural products. The strongest force behind the downward trend is seen to be manufactured export prices, which fell by half relative to the domestic price level. Both manufactured and agricultural import prices also declined relatively, while prices of agricultural exports underwent large short term fluctuations with no distinct trend. Prices of agricultural exports have been declining in most of the peacetime years since 1913, but large jumps during the two World Wars canceled out the years of decline.

TRENDS IN PRICES AND TERMS OF TRADE

A further breakdown into economic classes for the prewar and postwar years (Table 4) reveals even more impressively the pervasiveness of the decline in foreign trade prices. Every class but one has fallen in price relative to domestic output by the 1950's, some by only a little, others by almost 50 per cent or more. The contrary behavior of imports of crude

Source Derived from Appendix Tables A-1, A-3, and G-8

foodstuffs resulted from the great postwar increase in coffee prices. In 1959-60, however, even this class had fallen below the 1879-88 level.²³

The substitution of Paasche price indexes for the Fisher indexes before 1913 would have had very little effect. It would have eliminated the slight rising trend of relative agricultural export prices and most, or all, of the very mild drop in relative prices of manufactured imports.

The fact that the relative decline in foreign trade prices was concentrated in the 1920's and 1930's might argue for an explanation related to that period alone, rather than one involving more fundamental characteristics of foreign trade. But it is also possible that the concentration of the aggregate trend within a few years, rather than the trend itself, is the "accidental" feature of the series.

The behavior of prices for agricultural and manufactured products casts some light on the timing of the decline in the total index. Manufactured export prices fell quite consistently, relative to the domestic price level, from the 1880's to the 1930's, and then leveled off. Agricultural export prices rose slightly (in relative terms) before 1913. This rise canceled out in the total index most of the fall in manufactures prices, since agricultural exports were so much more important at that time. Agricultural export prices jumped more than 45 per cent during both World Wars and then fell. In the 1913-19 increase, agriculture was still important enough to carry the aggregate index with it. The sharp fall in aggregate prices after World War I was the result of price declines in both agricultural and manufactured products.

On the import side, both manufactured and agricultural products declined in price compared with the domestic index from the 1890's to the 1930's, and aggregate import prices declined with them. There was some recovery in both import price indexes following the 1930's, but a renewed decline began after the Korean War.

It would appear, then, that declining foreign trade prices were fairly widespread among commodity groups and over time, and that the main reversals of this decline, particularly for primary products, occurred in wartime.

In Chapter 2, this fall in export and import prices relative to the domestic price level is shown to be important in the analysis of the relations between the volume and value of trade and measures of domestic output.

²³ As in other cases mentioned earlier, the long-term decline in export and import prices may be exaggerated slightly by the difference in formula between foreign trade and domestic price indexes. Substitution of the Paasche indexes (Appendix A—Basic Tables) in Table 4 would have lowered the 1879-83 figures to approximately:

Imports of crude foodstuffs	109	Exports of crude foodstuffs	103
Imports of semimanufactures	86	Exports of manufactured foodstuffs	93

CHAPTER 2

Trends in Values and Quantities

THE foreign trade of the United States, like almost every other aspect of its economic life, has been characterized by persistent growth (Chart 9 shows the data since 1869). There were, it is true, periods of retardation and decline as well as sudden spurts and reversals that marked war and reconstruction periods. But the only major peacetime interruption of the climb was the great depression of the 1930's which cut into international trade even more deeply than into other areas of the economy. The interwar experience was unique in at least two respects. The severity of the decline in both export and import values and quantities had never been approached in peacetime, even in the depression of the 1890's. The failure to recover previous peak levels after ten or fifteen years was also unprecedented.

In the postwar years the amplitude of fluctuations and the length of recovery periods have returned to prewar levels.

Trends in the Ratio of Total Trade to Output

BACKGROUND OF THE PROBLEM

It has often been said that the economic development of a country reduces its dependence on foreign trade and that the spread of industrialization throughout the world tends to diminish the importance of international trade by reducing those differences in economic structure and skill which are the basis for profitable exchange.

Pervading this discussion has been the belief that international trade consists mainly of the exchange of manufactured goods from the developed countries for crude materials and foods produced by the undeveloped areas. The importance of international trade in the nineteenth century was therefore considered to be a temporary phenomenon. The eventual industrialization of the backward areas would result in the diversion of their export staples to domestic uses and in the replacement of imported by domestically produced manufactured goods.

This line of reasoning is related to classical theorizing regarding the future terms of trade between agricultural and manufactured products. The link between them is exemplified by a frequently quoted statement from Torrens to the effect that the price of crude products relative to manufactured goods would eventually rise within developing countries, as

it already had in the older countries, thus destroying the basis for the most profitable trade between them.¹ These predictions were echoed more than a century later by D. H. Robertson, who considered it evident that "we must learn to accomodate ourselves permanently to a smaller relative volume of international trade. . . ." The fact that "the scope for advantageous exchange between nations is narrowing" would not only diminish the relative volume of international trade but also encourage trade restrictions because the "narrowing of the gap of Comparative Advantage" would make the welfare loss from a reduction in imports less important compared to advantages in terms of, for example, stability.²

Similar pessimism about the future scope of international exchange had been expressed by German economists around the turn of the century, and for much the same reasons.³ Sombart, for example, stated that over a period of fifty or hundred years, civilized nations had become less interconnected through trade relationships, and less involved in world markets. Actually his evidence—very dubious estimates for Germany in 1830 and 1895—indicated no more than an unchanging trade-income ratio.⁴

¹ "As the several nations of the world advance in wealth and population, the commercial intercourse between them must gradually become less important and beneficial. . . . The species of foreign trade which has the most powerful influence in raising profits and increasing wealth, is that which is carried on between an old country in which raw produce bears a high value in relation to wrought goods, and a new country where wrought goods possess a high exchangeable power with respect to raw produce. Now, as new countries advance in population the cultivation of inferior soils must increase the cost of raising raw produce, and the division of labor reduce the expense of working it up. Hence, in all new settlements, the increasing value of raw produce must gradually check its exportation, and the falling value of wrought goods progressively prevent their importation; until at length the commercial intercourse between nations shall be confined to those peculiar articles, in the production of which the immutable circumstances of soil and climate give one country a permanent advantage over another." Robert Torrens, *Essay on the Production of Wealth*, London, 1821, pp. 288-289.

² "A narrowing of the gap of Comparative Advantage will not only diminish the volume of advantageous foreign trade, but will tend to produce a state of affairs in which there is a relatively large volume of foreign trade trembling, as it were, on the margin of advantageousness, and liable to be blown to one side or the other of that margin by small changes in the wind of circumstance. If, having been for some time just outside the range of profitableness, it is suddenly blown just within that range, great dislocation and distress will be caused to those who have laid their plans on the expectation of its remaining outside that range; and at the same time the benefit conferred on the community as a whole will be relatively small." D. H. Robertson "The Future of International Trade," *Economic Journal*, March 1938, pp. 7-8.

³ See Jacob Viner, "The Prospects for Foreign Trade in the Postwar World," *Transactions of the Manchester Statistical Society*, Annual Meeting, June 19, 1946, reprinted in Viner, *International Economics*, Glencoe, 1951, and in American Economic Association, *Readings in the Theory of International Trade*, 1949. These arguments are more extensively discussed in Albert O. Hirschman, *National Power and the Structure of Foreign Trade*, Berkeley, University of California Press, 1945.

⁴ Werner Sombart, *Die Deutsche Volkswirtschaft im Neunzehnten Jahrhundert*, 7th ed., Berlin, 1927.

TRENDS IN VALUES AND QUANTITIES

CHART 9

Value and Quantity of U.S. Exports and Imports, 1869-1960

This line of argument has been attacked on several grounds. Viner attributed any fall in the importance of international trade since the 1870's to the effect of increased tariffs, import quotas, and other "deliberate obstacles to international trade" rather than to any "natural factors".³ Other writers argued that the role of the "traditional" type of exchange—manufactured goods from industrial countries for foods and raw materials from undeveloped ones—had been exaggerated. They pointed to the importance of the exchange of agricultural products against other agricultural products and of manufactures against manufactures, or to the major importance of trade among industrial countries as compared to that between

industrial and nonindustrial ones.⁶ Eugene Staley presented national income and trade data (in current dollars) for several countries which showed little clear change in trade-income ratios before the 1930's.⁷ Mainly interested in proving that there had been no absolute decline in trade, he accepted relative decline as a fact, attributing it to the shift in consumer demand from goods to services as income increases. But he may have been influenced in this by the data for the 1930's, the last period he covered.

In a recent article, Deutsch and Eckstein⁸ reported that an increase in trade-output ratios during early stages of economic development, followed by a decrease in the later stages, has been a typical pattern. But their data for individual countries showed very diverse patterns. It is true that the

TRENDS IN VALUES AND QUANTITIES

latest years were not the highest of the whole period, but in several cases they were close to it. There was no rising period in the trade-output ratios for the U.S., and the rise for Germany rested on the virtually worthless Sombart figures mentioned earlier. In any case, a considerable effort of the imagination is required to discern among the violent war and interwar fluctuations and the rapid postwar increases in the ratio, a consistent pattern of a gradually rising trend followed by a declining one.

The same article attempts to assess trends in constant-dollar trade ratios between 1890 and 1934, but the results are vitiated by the use of a single (unexplained) deflator for the exports of all the countries listed. In the case of the United States, for example, Deutsch and Eckstein show a growth rate of 31.9 per cent per decade in the volume of exports, as compared with one of 33.8 per cent for national income. The NBER index, however, shows a growth in exports of 36.6 per cent per decade—higher than domestic output rather than lower.

The new NBER price and quantity indexes enable us to investigate the relations between trade and output in the United States for the last eighty years in real terms, as is done in the theoretical literature, rather than purely in money terms—the only possibility up to now.

We shall also glance at the period before 1879 by taking advantage of some recently constructed estimates of U.S. commodity output since 1839.

U.S. TRADE-OUTPUT RATIOS

When the export and import trade of the United States is compared with current value gross national product or commodity output, the expansion that was so evident in Chart 9 vanishes completely. Instead, the data seem to confirm the pessimistic predictions about the course of world trade—discussed earlier. Ratios of exports to GNP* (Table 5 and Chart 10) after fluctuating between 6 and 7 per cent during most years before World War I (slightly higher during the 1870s) dropped as low as half that

* Absolute levels of trade-output ratios cannot easily be translated into measures of the importance of foreign trade to the economy. There are differences in valuation, for example—foreign trade prices probably lying somewhere between the producers' prices of the Shaw data and the purchasers' prices of the Kuznets data. And there are difficulties in choosing a concept of output for individual commodities and narrowly defined industries; gross output is the closest to exports and imports, but becomes inflated by duplication as these are combined into larger industries or total output. Exports and imports are free of duplication in the sense that a product exported in crude form will not be exported again as a manufactured item, although it is true that a product imported as a crude material may be exported in processed form. The use of an unduplicated total such as finished manufactures is an imperfect solution because many exports and imports are in a crude or semimanufactured state. Value added, another possible denominator, is an attribute of industries rather than commodities.

TRENDS IN VALUES AND QUANTITIES

level during the 1930's and then recovered only to an average of about 5 per cent after World War II.

For imports the decline was even greater; the ratio to GNP in the 1870's ranged between 5½ and 9 per cent, averaging about 7 per cent. It fell in two sharp drops after 1871 and again after 1895, to a level of between 4½ and 5 per cent just prior to World War I. Another sharp drop after 1929 brought the ratio down to around 3 per cent, and the postwar recovery did not carry it much above 3½ per cent.

Values of international trade have been compared in the literature with several measures of output. Table 5 indicates that the conclusions drawn would not be substantially affected if any of three common measures were used. The ratios of trade to GNP (column 2) show the steepest decline, partly because GNP includes services, which were growing more rapidly than commodity output. From 1869-89 to 1930-39 the ratio of exports to GNP fell 47 per cent and that of imports 53 per cent.

Ratios to the Kuznets commodity flow series (column 3) declined less rapidly—by 44 and 50 per cent during the same period—but by 1948-57 they had virtually caught up with the GNP percentages. Trade declined least when measured against the Shaw series, 41 per cent for exports and 47 per cent for imports from 1869-89 to 1930-39.

In the twenty years before the Civil War, export ratios (based on Gall

TRENDS IN VALUES AND QUANTITIES

man's recently published estimates of commodity output),¹⁰ were somewhat lower on the average than in the rest of the years before World War I. Import ratios were, however, slightly higher before 1860 than after.

We may say, then, that there seems to have been a large and consistent decline, extending over a period of more than a century, in the ratio of the value of imports to the value of American domestic production. This decline has taken place mainly in several large jumps. Export ratios, comparatively stable before World War I, have been considerably lower ever since.¹¹

When the effect of price change is removed, a very different picture emerges of the relation between the quantity of trade and output since 1879.¹² Export ratios in 1913 dollars were at approximately the same level during the 1920's as before World War I; they were cut sharply after 1929, but regained their earlier levels after World War II (Chart 10 and Table 6). The postwar ratios have been above those of the 1880's and approximately equal to those of the 1890-1913 period; no downward trend is evident.

The behavior of the import ratio, too, was strikingly different when constant-price figures were used. After some decline between the 1880's and the 1890's, the import ratio rose and maintained, during the 1920's, a higher level than in the whole prewar period (in sharp contrast to the current-dollar figures).¹³ During the 1930's, when the current-dollar import

¹⁰ Robert E. Gallman, "Commodity Output, 1839-1899," *Trends in the American Economy in the Nineteenth Century*, Studies in Income and Wealth, Vol. 24, Princeton University Press for NBER, 1960.

¹¹ The difference in trend between export and import ratios is a reflection of the shift in the international capital position of the United States.

¹² Lacking export and import price indexes for earlier years, we cannot study quantity relationships before 1879. Douglass C. North has recently published new export and import price indexes for the period 1790 to 1860 in *The Economic Growth of the United States, 1790-1860*, Englewood Cliffs, N.J., 1961. But the tasks of linking these to indexes for later years and filling the gap between 1860 and 1879 still remain. The existing indexes for these years, discussed in the Introduction, appear too weak to support any conclusions regarding long-term trends.

¹³ This seems to contradict the general impression. For example, in Don D. Humphrey, *American Imports*, New York, 1955, a chart on p. 19 and a table in Appendix 1, p. 527, show a fall of 38 per cent between 1890 and 1919 in the ratio of imports to finished commodity output in constant dollars (Shaw's data). Our figures indicate virtually no change in this interval. The difference between the two findings arises mainly from Humphrey's use of the U.S. Wholesale Price Index to deflate imports. The Wholesale Price Index rose 147 per cent during these years, considerably more than the implicit index underlying his denominator (Shaw's series for finished commodity output destined for domestic consumption), which rose only 119 per cent. Our import price index, in contrast, rose less than the implicit deflator—only 85 per cent. Humphrey was aware of the possibility of bias in his deflator but apparently felt that the Kreps index (T. J. Kreps, "Import and Export Prices in the United States and the Terms of International Trade, 1880-1914," *Quarterly Journal of Economics*, August 1926), which was the only one available at the time he wrote, was overly dominated by coffee, sugar, and wool (see Humphrey, *American Imports*, note p. 20 and p. 99).

TRENDS IN VALUES AND QUANTITIES

ratio fell to half the level of the 1880's, the quantity ratios were the highest since 1879. Only after 1937 did the constant-dollar import ratios drop sharply, falling by a third within five years, to the lowest levels in our record. After World War II, they began to climb sharply until, in the years 1958-60, they again reached a level similar to that of the 1880's.

Over the whole period, then, the only suggestions of a downward trend in the ratios of the quantity of trade to output were the low interwar export and postwar import ratios. Both now appear to have been temporary. It is clear, therefore, that the well known decline in the value ratios has been largely a price phenomenon. It is a reflection of the fact, pointed out in Chapter I, that both import and export prices have fallen, in the long run, compared with domestic prices.

Thus, although current value export ratios have followed roughly the pattern expected by Sombart (and others mentioned earlier), ratios for

TRENDS IN VALUES AND QUANTITIES

current-dollar imports and constant-dollar exports and imports for the United States appear to contradict his thesis. It is in real terms that the pessimistic outlook for the future of international trade has usually been stated and theoretically justified.

Agricultural Trade and Output

BACKGROUND OF THE PREWAR AGRICULTURAL EXPORT TRADE

Despite increasing industrialization after the Civil War, agricultural exports were predominant in U.S. trade throughout the nineteenth century. For almost 100 years, until the early 1890's, agricultural products were 73 to 83 per cent of total exports,¹⁴ and even at the beginning of World War I they still accounted for almost half. Thus, agricultural exports virtually kept pace with the rapid growth of industrial exports almost to the end of the nineteenth century. At that time, their share of total exports began a fifty-year decline, leveling off only during the last few years at a little over 20 per cent.

Since agricultural exports played so large a role, the development of American trade during this period must be studied against the background of shifting and interacting supply and demand conditions for agricultural production in the United States and her chief market—Europe. These supply and demand changes were interrelated; long-term shifts in supply conditions encouraged and yet depended on the changes in demand.

The changes on the demand side were such familiar economic events of the nineteenth century as the growth of cotton textile manufacturing, the urbanization and industrialization of Europe with the attendant growth of income and the decline of European agriculture.¹⁵ The Eastern seaboard of the United States played the same role vis-à-vis the West that Europe played in relation to the United States as its population shifted from rural to urban areas and from agriculture into manufacturing.

On the supply side, the second half of the nineteenth century represented the climax in the development of American agriculture and the agricultural export trade. Farm output grew at a rapid and fairly constant rate throughout the nineteenth century,¹⁶ but it slowed down at the

¹⁴ *Foreign Commerce and Navigation of the United States*, 1902, p. 73.

¹⁵ Some of these developments are summarized in Edwin G. Nourse, *American Agriculture and the European Market*, New York, 1924, pp. 8-42 and 239-276.

Rasmussen, "Farm Gross Product and Gross Investment in the 19th Century," *Trends in the American Economy in the Nineteenth Century*, Studies in Income and Wealth, Vol. 24, Princeton University Press for NBER, 1960. Some of the constancy in the rate of growth may have been imparted by the estimating procedure.

TRENDS IN VALUES AND QUANTITIES

beginning of the twentieth century and never regained its earlier rate¹⁷ Agricultural productivity and output per capita increased faster in the second half of the century than in the first, per capita output reached levels that were never attained again¹⁸

The growth of farm output was associated with great expansions in the farming area of the United States The land added to farms in the fifty years ending in 1900 was almost twice the 1850 acreage, and almost equaled that added in all other years After 1900, growth in the farming area slowed considerably¹⁹

The major increases in farm output, and particularly those in the major export products, involved not only expansions in the farming area but also large scale migrations of production to new areas In the first half of the century the major migration was that of cotton production from Georgia and South Carolina (the original producers and still responsible for more than half of the output in 1820), to Mississippi, Louisiana, Texas, and Arkansas which accounted for most of the increase in output after the 1830s²⁰

The migration of grain and meat production was the outstanding feature of the second half of the century In 1850 the North and South Atlantic states accounted for more than half the wheat and oats, almost half the cattle (other than dairy cattle) and over 30 per cent of corn output and swine Only 14 per cent of the swine, 15 per cent of the cattle, and 12, 6, and 5 per cent of the corn, oats, and wheat, respectively, were accounted for by the states west of the Mississippi By 1900 the share of the Atlantic states in all of these products had fallen to 10-13 per cent, west of the Mississippi it ranged from 48 per cent for oats to 65 per cent for wheat and 70 per cent for cattle²¹

Accompanying the westward expansion of agriculture was the growth of railroad mileage, which more than doubled between the end of the Civil War and 1879, more than redoubled by 1899, but increased much more slowly thereafter²² With the forging of railroad connections both the eastern United States and Europe were brought economically closer to the

TRENDS IN VALUES AND QUANTITIES

West by falling freight rates. For example, rates for the shipment of wheat from Chicago to New York by lake and canal fell by more than 50 per cent between 1860 and 1879 and by another 50 per cent from 1879-1899; rail rates for the same product fell by 50 per cent between 1869 and 1879 and about 30 per cent more by 1899.²³ Ocean freight rates for American exports also fell drastically during the nineteenth century, particularly before 1850 and after 1870.²⁴

With rapidly increasing production and falling prices and transportation costs, American grain and meat products invaded European markets. American wheat, for example, drove both German and Russian wheat from the English market during the 1860's and 1870's, and supplied more than half of British wheat imports to the end of the 1800's.²⁵ In a similar way American meat products captured the British market from European suppliers who had dominated it before the 1870's, although the newer exporting areas, such as Argentina and Australia, began to challenge the American position toward the end of the century.²⁶

After the 1890's there was a sharp reversal in the agricultural situation. The expansion in the farming area slowed, and the increase of farm production, which had raced ahead of the growth of population in the 1870's and more than kept pace with it during the 1880's and 1890's, began to lag behind. The quantity of agricultural exports, which had multiplied several times since the Civil War, began to fall slightly, while agricultural prices recovered from their long post-Civil War decline and began to rise more rapidly than other prices. European countries turned to new sources of food: Canadian, Indian, and Australian wheat; Argentine beef; and Canadian and Danish bacon, for example, all began to supplant American products in the British market.

TRENDS IN U.S. EXPORTS AND OUTPUT OF AGRICULTURAL PRODUCTS

Values of U.S. agricultural exports after World War II were ten times those of the post-Civil War period and triple those of the years just before World War I (Chart 11). Only the depression of the 1930's reversed the

TRENDS IN VALUES AND QUANTITIES

trend for any length of time, slashing export values to 40 per cent of those in the 1920s and reducing them below the average value of the decade before World War I. The advance in general was an uneven one, slowing during the 1880s and 1890's and accelerating during the two wars.

The quantity of agricultural exports showed no such growth. Its rapid increase until the late 1890's—much faster than the values—was followed

CHART 11

Value of US Agricultural Exports, Current and 1913 Dollars

Source: Appendix Table A 7.

TRENDS IN VALUES AND QUANTITIES

by a long period of stagnation. The levels just after World War II were no greater than those of the 1890's, more than fifty years earlier. Only recently have exports of agricultural products come to life again, growing, at least for a few years, at a rate reminiscent of the nineteenth century.

Because of this lack of growth over so many years, the quantity of agricultural exports declined relative to total national output. The extent of this fall is shown in Chart 12. Before 1900 agricultural exports were almost always above 5 per cent of deflated GNP—slightly higher in the 1870's than in the eighties and nineties. By the 1930's, a long, steady decline had carried them below $1\frac{1}{2}$ per cent of GNP. They have remained roughly at this level since that time. Data for current-value ratios, not shown in the chart, tell much the same story.

There are two possible explanations for this reduction in the importance of agricultural exports. It might have reflected the shifting of resources out of agriculture within the domestic economy, or it might have implied a shift within U.S. agriculture away from dependence on foreign markets and toward reliance on domestic consumption.

Over the period as a whole, as can be seen in Chart 12, the first factor was the crucial one. The decline in agriculture's share of gross national product is much steadier than, but roughly parallel to, the decline in the ratio of agricultural exports to GNP. This rough, long-run agreement is reflected in the fact that the ratio of agricultural exports to agricultural gross product shows no long-term trend.²⁷

Despite the fact that the fall in agriculture's share of gross output explains the long-run fall in the ratio of agricultural exports to GNP, some very substantial shorter-term changes in the ratio remain to be accounted for. There is, in particular, the contrast between the steady decline in the domestic position of agriculture since 1869, and the failure of agriculture's share of exports, measured in constant or current dollars, to decline until the 1890's. This contrast reflects a considerable shift toward foreign markets for farm products; agricultural exports rose from about one-eighth of agricultural gross output just after the Civil War to a peak of roughly one-quarter at the end of the 1890's. After that, however, the

²⁷ This ratio is only a crude measure of the importance of export trade to farm income. On the one hand it tends to overstate the importance of exports because an agricultural product will have a higher value at the port of shipment than at the farm. Even if the product has not been processed, the export price includes value added by the transportation and, perhaps, the wholesale trade or service industries. Processed farm products contain value added in manufacturing as well.

On the other hand, the export ratio tends to understate the role of international trade because many products of agricultural origin, such as textiles and leather goods, drop out of the agricultural class between the farm and the port of export.

TRENDS IN VALUES AND QUANTITIES

CHART 12
Relations of Agricultural Exports, Agricultural
Gross Product, and GNP, 1913 Dollars

Source: Appendix Tables G-10, G-12, and G-14

foreign share began to fall; following a brief rebound during World War I, it plummeted during the thirties to the lowest level since before 1869. World War II again lifted the ratio, which has continued to rise erratically toward the prewar levels.

The high ratio of exports to gross income within agriculture in the 1890's represented a peak not only for the post-Civil War years but apparently for the nineteenth century as a whole, judging from current-dollar data on agricultural production. A comparison of agricultural exports with the Towne-Rasmussen output series,²⁸ shows that the ratio rose from 11 and 12 per cent in 1800 and 1810 to 13 per cent or more in 1840 and 1850, almost 18 per cent in 1860, and between 20 and 23 per cent in 1880-1900.

The significance of the foreign market to American agriculture is only partially indicated by the level of these ratios, even apart from the ambiguities in them mentioned earlier. Exports were much more important for some crops than for others and were particularly important to individual products when their output was expanding most rapidly. It might be said that the existence of a broad foreign market made possible some of the great spurts in production by providing an incentive to produce goods which could have been sold on the domestic market only at much lower prices.

Cotton, which dominated U.S. agricultural exports before 1860, is the prime example of an export-dependent commodity. During the period of the most rapid growth in cotton production, between about 1815 and 1840, the export ratio rose to almost 80 per cent and remained near that mark. From 1870 to World War I output grew somewhat less rapidly than before the Civil War, and the export ratio fell to 65-70 per cent. Production leveled off after that, and the export ratio continued to fall, until in recent years it has rarely been above 40 per cent.

After supplying 80 per cent of the increase in agricultural exports between 1800 and 1860, cotton lost its leading role and provided only 14 per cent of the growth over the last forty years of the century. The main role then shifted to grain and meat products, which accounted for over 70 per cent of the increase between 1856-60 and 1895-99. Production data show that the growth in cotton output slackened after the middle of the century; the growth of output of food grains, feed grains, and livestock accelerated.²⁹ Per capita output of food and feed grains and livestock hardly changed from 1800 to the 1850's. After that all three rose until the 1890's and then declined until the beginning of World War I. Except for cotton,

²⁸ "Farm Gross Product."

²⁹ *Ibid.*, pp. 282, 292.

TRENDS IN VALUES AND QUANTITIES

the peak in exports and export ratios coincided with that brief period when production ran ahead of the increase of population. The peak in cotton export ratios coincided with the most rapid increase in per capita output.

The story can be put in another way. The pattern of exports for the major food items can be at least roughly inferred from the output data by assuming constant per capita consumption. This stability in consumption, in the face of changing farm prices and growing real incomes, suggests that domestic price and income elasticities were low, as might be expected. These low elasticities imply that the absorptive ability of the foreign market was a prerequisite for the great expansion in American agriculture after the Civil War.³⁰

Some further data on individual commodities emphasize the role of export trade in the expansion of agricultural output after the Civil War. Exports of pork products were never very high relative to farm income from hogs: less than 7 per cent in 1869-73, 21 per cent in 1899-1903, and 17 per cent in 1904-8. But of the increment in gross income between the first and last of these periods, exports supplied 57 per cent, and the increase in exports between the first and second periods was greater than the growth in gross income. Corn exports rose from a little over 10 per cent of production entering gross income in 1869-73 to over 20 per cent in 1899-1903, and the addition to exports was about 26 per cent of the addition to production. Exports were always important relative to wheat output—some 24 per cent in 1869-73 and 36 per cent in 1894-98. But they were still more important in the increment to production—almost 50 per cent in the same period.

For some commodities, foreign trade, then, quickly provided an extensive market which could only have been created much more slowly by the growth of the American economy itself. In this respect American development depended on the willingness of the older industrial nations, particularly the U.K., to permit their domestic resources to be shifted out of agriculture by the influx of cheaper products from the developing areas.

TRENDS IN U.S. AGRICULTURAL IMPORTS

Agricultural imports, like exports, have shown a large long-term increase in values (Chart 13). The short-run similarity between the two value series, however, is mainly imposed by large price movements such as those

³⁰ It should be noted that the crude assumption of constant per capita consumption will not serve at all for cotton. The export ratio fell after 1840 while output per capita was still increasing.

TRENDS IN VALUES AND QUANTITIES

CHART 13

Value of U.S. Agricultural Imports, Current and 1913 Dollars

Source: Appendix Table A-7.

during the two world wars. Over the long run, agricultural exports rose much more than imports in price, but rose much less in quantity.

Agricultural imports in 1913 dollars increased rapidly, and at a remarkably steady rate, before World War I. They showed none of the sharp fluctuations that were present in exports and no retardation after the 1890's. The interwar period found them between 50 and 100 per cent

above the prewar level, even during the 1930 s²¹ and they remained in this range after World War II

The great swings in the agricultural import value series were almost entirely in prices—even the tripling or more in value that took place during and after World War II. Despite the turbulence of the years that followed World War I the volume of agricultural imports hardly ever moved more than 15 per cent above or below the level of the 1920 s. Relative to GNP, the value of agricultural imports declined before World War I, particularly during the 1890 s, and continued to fall in the interwar and postwar years (Chart 14). But the quantities behaved very differently. Their ratio to deflated GNP was very steady before 1913 and then jumped to a considerably higher level, which was sustained through the 1930 s. Only after 1937 did they really decline—far below earlier levels—and the decline has persisted until recent years.

Since agriculture was so steadily declining in importance in the domestic economy all these trends are rotated counterclockwise when comparisons are made with gross farm output rather than GNP. Thus the volume of agricultural imports rose sharply relative to gross farm output in the prewar period. Even import values increased somewhat in comparison with current-dollar agricultural gross income. Imports in the interwar and postwar periods were higher relative to domestic farm output than before World War I in both quantities and values, particularly in the former. Despite the downward drift in the ratios, they still remain considerably above those of prewar days.

The growth of agricultural imports in comparison with agricultural output and exports cannot automatically be assumed to represent the result of direct competition between imports and domestic products. The two groups contain very different commodities and some of the largest appear on only one side of the account. Much of the competition between domestic and foreign agriculture is of a sort not revealed by foreign trade data, it is competition within the US between imports and domestically-produced crops and in other countries, between exports and foreign produced products.

Trade in Manufactured Articles

It is difficult to date the end of agricultural predominance in exports and the beginning of the rise of manufactures. Our series indicate that the

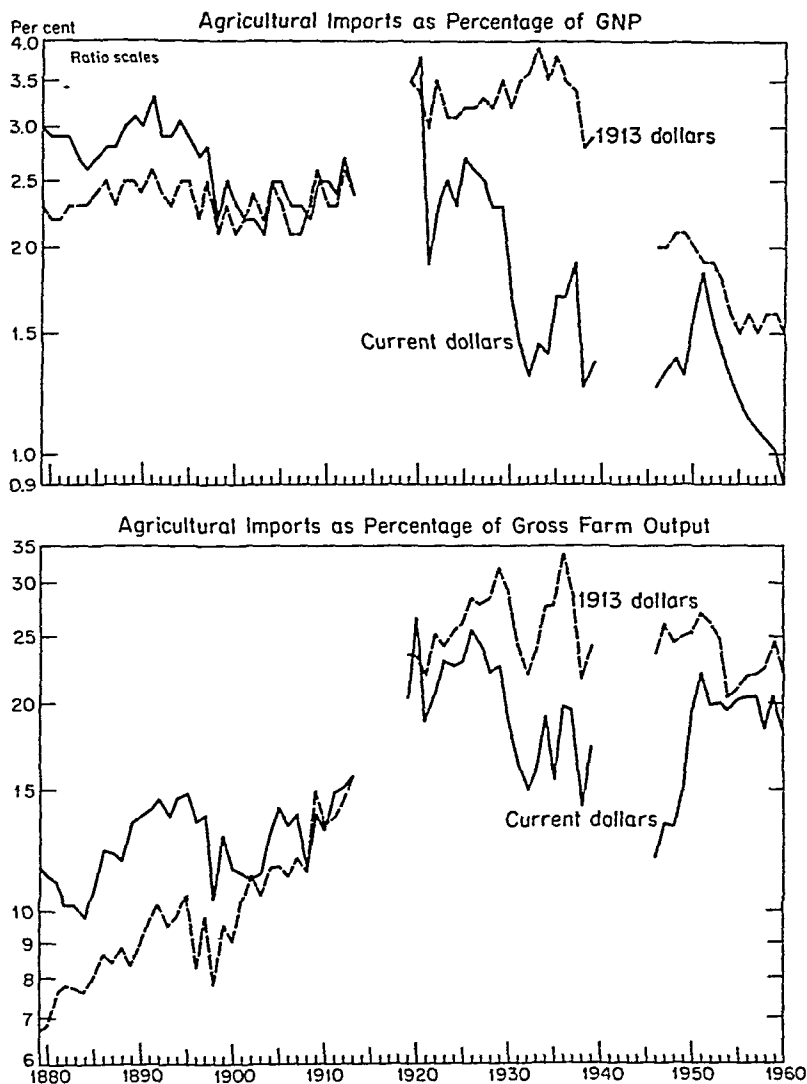

²¹ There is some evidence that agricultural imports in the 1930 s were sustained by the severe drought which afflicted the grain-growing areas of the United States. See John H. Adler, Eugene R. Schlesinger and Evelyn Van Westerborg, *The Pattern of United States Import Trade Since 1923*, Federal Reserve Bank of New York, 1952.

TRENDS IN VALUES AND QUANTITIES

share of agricultural products in total exports remained almost unchanged from 1800 through the early 1890's (despite the relative decline of agriculture in the labor force and in national income).

Only after the 1890's did it begin to fall steadily. This constancy in the share of agricultural products in exports is partly conceptual : we consider

CHART 14
Agricultural Imports as a Percentage of Farm and Total GNP,
Current and 1913 Dollars

Source: Appendix Tables G-12 and G-14.

TRENDS IN VALUES AND QUANTITIES

as agricultural a number of manufactured foods, such as flour and meat, which are treated in income and labor force statistics as products of manufacturing. Ideally, the export values should be divided among the sectors (including transportation) in proportion to their contribution to value added up to the point of export.²²

It is possible to roughly estimate the effect of applying the domestic industry classification to the trade figures. Excluding manufactured foods, the share of agricultural products in total exports ranged from 60 to 70 per cent until the late 1870's,²³ and then began to fall. In other words, the share of manufactured foods in agricultural exports (as defined here) began to increase in the 1870's. Between 1820 and 1870 it had varied generally between 14 and 25 per cent, and had been close to 15 per cent in the years just before and after the Civil War. Subsequently the share began to rise, reaching 37 to 39 per cent in the middle 1890's, thus offsetting the falling importance of crude agricultural products. The ratio of manufactured food to total agricultural exports fell below 30 per cent after 1908. It was again below that level during the interwar period but has frequently been higher since the beginning of World War II.

The inclusion of certain products of manufacturing industries in agricultural exports requires some explanation. Aside from reasons of convenience, such as the fact that crude and processed foods are customarily combined in international trade statistics, there is an economic argument as well. As illustrated in Table 7, the food industries which supplied the main items of exports, meat packing and flour milling, had a comparatively small part of their total value added in manufacturing. Costs other than purchased materials accounted for only 12 to 16 per cent of the total output in these industries, and most of the materials purchased came from agriculture. In all other industries combined, despite the fact that some food industries are included, costs other than purchased materials accounted for 41 to 49 per cent of the value of output. Furthermore, many of the materials were obtained from other manufacturing industries rather than from agriculture.

Because of the very large role of purchases from agriculture in the total value of manufactured food products, agricultural developments appear

²² This can be done using the type of data assembled for an input-output table. See, for example, Conference on Research in Income and Wealth, *Input-Output Analysis, Technical Supplement*, New York, NBER, 1954, Chap. 3. But such tables would be needed, not for one year, but for a historical series.

²³ This is a rough estimate made by subtracting manufactured foods from total agricultural products. It is too low by amounts between 1 and 5 per cent, judging from the evidence of the period after 1879, because some of the manufactured foods subtracted had never been included in the agricultural total.

TRENDS IN VALUES AND QUANTITIES

more relevant for understanding the trade in manufactured foods than changes within manufacturing.

Despite the industrial development of the United States, exports of manufactures (nonfood manufactured products) had not, by the late 1890's, encroached substantially on the overwhelming share of agricultural products. In the next fifty years, however, manufactures became the leading export, accounting for more than all the other classes combined (Chart 15). Since World War II, the share of manufactures in total exports seems to have leveled off at about 60 per cent.

The ratio of manufactured exports to deflated GNP behaved similarly; it grew rapidly over the period as a whole, reaching its highest levels in the postwar period. But again, there is no evidence of a rising trend within the postwar years.

The rise of manufactures to a leading role in exports was partly a reflection of the increasing importance of manufacturing in the economy,

TRENDS IN VALUES AND QUANTITIES

as exemplified by its growing share of the labor force and of national income. But the share of manufactures increased much more rapidly in exports than in the domestic economy as the growth of manufactured exports outstripped that of manufacturing output.

This difference in rate of growth is reflected in the ratio of exports to gross manufacturing output,²⁴ which more than doubled between the early years

CHART 15
Trade in Manufactures Compared with Total Exports
and Imports and GNP

²⁴ This calculation is more hazardous for manufactured than for agricultural products because the valuation questions are more important (see footnote 10). We have evaded the problem posed by valuation by comparing only indexes of export and import quantities and manufacturing output.

The ratio of value added to value of product is much higher in agriculture than in manufacturing. Therefore, the comparison of exports, which are a value-of-product measure, with gross output, which is a value added measure, is more appropriate for the farm sector. Comparisons of exports and imports with value of production, by industry, were made in an unpublished study by Phyllis A. Wallace, reported on briefly by Solomon Fabricant in the National Bureau's 33rd Annual Report, May 1953, pp. 77-78. Some of the results of this study were published in an article by Irving B. Kravis on "Wages and Foreign Trade" in *The Review of Economics and Statistics*, February 1956.

TRENDS IN VALUES AND QUANTITIES

of our period and 1911-13 and rose another 50 per cent by the postwar period (Chart 16).

Manufactured products are an enormously varied collection of commodities, ranging from the simplest transformation of agricultural or mineral products to complex machinery or scientific equipment in which the cost of the original raw material is insignificant. The composition

CHART 15 (Concluded)

Source: Appendix Tables A-6, A-8, A-10, and G-13.

of manufactured exports has been changing ceaselessly since 1879 in a fairly consistent direction—away from products of animal or vegetable origin and toward those of mineral origin. Among those of mineral origin, the trend has been away from commodities closely tied to the production of raw materials, such as petroleum products, to metal products, including

TRENDS IN VALUES AND QUANTITIES

machinery and vehicles, and within the metal products group the shift has been to the more complex machinery and vehicles

In 1879-81, manufactured petroleum products and articles of animal or vegetable origin (mainly textiles, wood, and tobacco products) represented more than 65 per cent of American exports of manufactures, while all metal products accounted for only 21 per cent. But the leading commodities of 1879 contributed very little to the great surge in manufactured exports that followed of the increase between 1879-81 and 1910-13, petroleum products, which were over 40 per cent of the total at the beginning, contributed only 13 per cent, textiles, which had been 16 per cent, added only 8. Metal products were responsible for 73 per cent of the gain, and doubled their share.

By the end of World War II, commodities of agricultural origin had dwindled still further in importance. Petroleum products had fallen to 5 per cent of the total, while metal products had soared to over 60 per cent. By 1957, petroleum and textiles combined were less than 8 per cent of manufactured exports, and textiles had declined even in absolute terms. The metal products group reached two-thirds of manufactured exports and, in 1949-1957, accounted for almost 75 per cent of the growth in this class.²⁵

The very steep rise in exports of manufactures was not matched on the import side, although imports have increased almost continuously since 1870. Rapid advances occurred immediately after both world wars, the recent increase considerably surpassing the earlier one in quantity and, even more, in value and length.

For about seventy years (from 1879 to 1950), the share of manufactures in total imports showed a declining trend (Chart 15), except during the late 1920's, when skidding prices reduced the share of agricultural imports. Since 1950, however, manufactures have jumped from 17 per cent of imports to more than 35 per cent—considerably above the levels of the 1880's. One must go back to the early 1870's to find percentages as high.

²⁵ Many complex phenomena are buried in this summary. For example, the United States has steadily lost ground as a supplier of petroleum products according to the usual international trade statistics. But American-owned companies continue to supply capital, entrepreneurship, and technical skills for petroleum production abroad.

Another interesting case is that of rubber products exports, the main component of which was automobile and truck tires. Despite the growth in use of automobiles outside the United States between 1949 and 1957, this class did not even keep up with total manufactured exports. But exports of synthetic rubber, which appears among semi-manufactures, grew more than tenfold in the same period. Both groups consist of rubber products which are the output of domestic manufacturing industry and which contain a large technological component, but the shift from a finished to a semifinished product reduces the manufactured goods category.

TRENDS IN VALUES AND QUANTITIES

The ratio of manufactured imports to GNP in 1913 dollars also suffered a great decline from the 1880's to the late 1940's. It has recovered strongly since then, reaching the level of the 1880's in 1959 and 1960.

By comparison with domestic gross output in manufacturing, imports of manufactures had dwindled by the early postwar years, to less than one-quarter of the 1880-89 level (Chart 16). Since then they have recovered to the level of the 1920's but not to that of the prewar period.

CHART 16
Ratio of Manufactured Export and Import Quantity Indexes
to Manufacturing Output Index
(1913 ratio = 100)

Source: Appendix Tables A-2 and A-4, and John W. Kendrick, *Productivity Trends*, output index on a 1913 base. (1955-60 from unpublished Kendrick tables.)

Imports of manufactures, like exports, have changed radically in composition. In both 1879-81 and 1890-94, textile products alone accounted for more than two-thirds of the total; by 1910-13 they had fallen to a half, and by 1949 to 20 per cent. Paper and paper products rose from 6 to more than 36 per cent, and metal manufactures from 8 to 13 per cent between 1910-13 and 1949.

The postwar resurgence of manufactured imports is of interest for a number of reasons. One is that reversal of the long-standing trend away

from manufactures would have implications for the stability of import demand and prices and for the U S balance of trade with other industrial nations Another is that the changing composition of imports since 1949 has involved shifts almost identical with those in exports—away from products of agricultural or organic origin and towards products of mineral origin, particularly metal products (including machinery and vehicles) Textile and paper products, which constituted 60 per cent of all manufactured imports in 1949, shrank to 35 per cent by 1958, and accounted for only 22 per cent of the increase in imports of manufactures But machinery, vehicles, and other metal products, the mainstays of American manufactured exports, increased their share of manufactured imports from 13 per cent to over a third during the same period, and were responsible for over 44 per cent of the increase in manufactured imports

Price-Quantity Relations

K3

PRICES AND QUANTITIES WITHIN U S TRADE

We have collected in this study an array of matched price and quantity data covering a wide variety of commodity groups within U S exports and imports No attempt has been made, except in a few cases, to go beyond U S trade data for the information on incomes and prices in other countries which could be built into a more complete analysis of price-quantity relations And no attempt has been made to estimate the underlying supply and demand elasticities

57421

It has become a commonplace that a set of price-quantity observations cannot be assumed to trace out either the supply curve or the demand curve However, these observations can be and are used to suggest inferences about the underlying functions³⁶ Here we will only call attention to some of the empirical regularities in the data, and offer a few tentative explanations or interpretations of them In particular we shall note the pervasiveness and strength of negative relations between prices and quantities, particularly over the long run

This section deals only with evidence for commodity aggregates Some inferences concerning price-quantity relations for individual commodities are drawn in Chapter 3 By examining the relation between Paasche and

³⁶ A recent example is an attempt to infer supply elasticities from price and acreage data for British wheat in the prewar period See Mancur Olson, Jr., and Curtis C Harris, Jr., 'Free Trade in 'Corn' A Statistical Study of the Prices and Production of Wheat in Great Britain from 1873 to 1914' *Quarterly Journal of Economics*, February 1959

Laspeyres price indexes, we find that substitution in favor of commodities with relatively declining prices was an almost universal feature in total exports and imports and within virtually all of the commodity classes.

The expectation of inverse price-quantity relations usually involves the response to relative price changes of relative quantities sold. But before 1913 there are quite clear examples of inverse relations between absolute volumes and prices for total exports and individual commodity classes. Total exports, for example, showed a rising trend from 1879 to 1913 (Chart 17). But there was a noticeable slackening in the rate of growth after 1898—the year in which export prices ended their long post-Civil War decline and turned upward. Before 1898 the only marked reversal in the growth in quantity was in the early 1880's. This was accompanied by a corresponding temporary reversal in the price decline.

Over shorter time periods, some parallel, instead of inverse, price and quantity movements emerge. Two sharp increases in export quantities (which occurred in 1888-92 and 1895-98, during the long-term downswing in prices) were accompanied by pauses in the price decline rather than by severe price cuts.

Exports of agricultural products and manufactured foods exhibit negative price-quantity relations more clearly, without the obscuring presence of strong trends. The period of rising agricultural exports coincides with the period of falling prices between 1882 and 1897-98, after which time, quantities declined slightly until World War I. It was as if the rising prices after 1898 (which, as noted in Chapter 1, were associated with a slowing in the growth of output and a decline in per capita output) choked off the growth of exports. Once again, however, short, sharp rises in export quantities temporarily stabilized prices in the course of the long-term decline.

For manufactured food exports, the period of rising prices before World War I was clearly associated with a decline in quantities rather than a retardation or cessation of growth. Again, short spurts in export quantities seemed to bring a slight increase in prices.

The difference between the long- and short-term patterns of price-quantity behavior suggests that the long-term changes represented shifts mainly in the supply function and the short-term changes, shifts mainly in the demand function. One would expect a negative price-quantity relation from the former and a positive one from the latter.

In the sphere of relative, instead of absolute, price-quantity relations a striking illustration was given by Folke Hilgerdt²⁷ of the inverse relation between the relative prices of primary and manufactured products and

²⁷ *Industrialization and Foreign Trade*, p. 18.

TRENDS IN VALUES AND QUANTITIES

CHART 17

Price and Quantity Indexes for U.S. Total, Agricultural, and Manufactured Food Exports

Source: Appendix Tables A-1, A-2, and A-5.

their relative quantities in international trade. Using three- to five-year averages, he showed that prices of primary products relative to those of manufactured goods fell between 1876-80 and 1896-1900, between 1911-13 and 1921-25, and between 1926-29 and 1931-35; they rose between 1896-1900 and 1911-13, between 1921-25 and 1926-29, and between 1931-35 and 1936-38. In each case the relative quantities moved in the opposite direction.

Hilgerdt's method of estimating quantities was probably biased in favor of an inverse price-quantity relationship. He constructed his estimates by deflating the value of world trade in manufactured goods by a price index. This price series, which related to Great Britain alone during much of his period, was probably a poor approximation of the true world price index, as we have suggested in Chapter 1. To the extent that it was, Hilgerdt introduced in his quantity estimates spurious changes inverse to those in the price index.³⁸

However, we have encountered similar inverse relations in many instances where the likelihood of such bias was much smaller. A purely technical explanation, therefore, seems inadequate; an economic one is required.

Over short periods, changes in demand might be expected to outweigh those in supply. Yet, inverse price-quantity relations between primary (or agricultural) products and manufactured goods are frequent. One explanation is that supply elasticities are lower for agricultural than for manufactured products. As a result, the effects of changes in demand will appear mainly in prices for primary products, but in quantities for manufactured goods. Thus, in both world wars prices of agricultural products far outdistanced those of manufactured goods, but quantities lagged behind. In the early 1930's, prices of manufactured goods fell much less than agricultural prices but quantities dropped more sharply. Some of these inverse movements go beyond short periods and encompass swings of ten or twenty years' duration.³⁹ Presumably these represent changes in supply conditions.

Along the same lines as Hilgerdt we have compared manufactured and agricultural products within exports and within imports. The export and import price trends differed markedly, as has been mentioned earlier. Within exports, manufactured goods became cheaper by comparison with

³⁸ The danger of spurious correlation is discussed further in Chapter 4.

³⁹ The influence of differences in supply elasticities may persist over longer periods because of differences in ease of entry and exit between agriculture and manufacturing. See Kindleberger, *The Terms of Trade*, pp. 227-231.

TRENDS IN VALUES AND QUANTITIES

agricultural products, *within imports* they became more expensive. Since the 1930 s, the direction of the import trend has been reversed.

Changes in export quantities have been broadly the opposite of those in prices (Chart 18). Over the long run the quantity of manufactured exports has increased rapidly relative to that of agricultural products, while the price of manufactured goods has fallen. Even the rate of growth of manufactured exports seems to have been related to price changes. After 1882, both quantity and price ratios were comparatively stable for ten or twelve years. Between the 1890 s and 1913, manufactures prices fell and quantities rose rapidly relative to agricultural products. The interwar period was dominated by large fluctuations in the price and quantity ratios, mostly in opposite directions. Relative quantities of manufactures fluctuated about a higher level, and prices about a lower level, in the interwar period than in prewar years. In the postwar period manufactured exports were again much higher, relative to agricultural exports, while the price ratios hovered around the lowest level of the interwar period. *Postwar short term fluctuations, in relative quantities and prices, however, seem to have been completely independent.*

The shares of manufactured and agricultural products in total exports have fluctuated inversely to the price ratios. Like the quantity and price ratios, they were stable for a time after 1882. Between the 1890 s and 1913, the share of manufactures rose from 20 to over 30 per cent, while the relative price of manufactured exports declined.

Within imports, inverse behavior of prices and quantities was much less visible, even quite large movements in one variable were without reflection in the other (Chart 19). But taking whole periods at a time, one can observe the phenomenon here too.

The strength of the inverse relationship in Chart 18 is not easy to explain, since agricultural and manufactured exports do not, to an important extent, *compete with one another for markets*. There are some elements of competition, however: all industries compete for some resources and, to some extent, all commodities compete for the consumer's dollar. In addition, there may be a choice as to whether a particular product should be exported before or after processing. The decision would be affected by changes in the productivities of processing industries. For example, in the last half of the nineteenth century a larger and larger proportion of wheat was exported as flour. The change presumably was linked to the increasing efficiency in the US flour milling industry.

Within agricultural products, where substitution between exports and

TRENDS IN VALUES AND QUANTITIES

imports is plausible,⁴⁸ no trend appears in the quantity or price ratios before 1900 (Chart 20). But from then until the late 1930s, agricultural export prices rose steeply in comparison with imports, and export quantities fell even faster. After World War II the price ratio reversed direction and fell most of the way back to the 1913 level, while the quantity ratio regained most of its loss since that date.

CHART 19
Ratio of Manufactured to Agricultural Import
Price and Quantity Indexes
(1913 ratio = 100)

Source: Appendix Tables H 9 and G 15

At first glance the relation between export and import price and quantity ratios for manufactures appears weak before World War II because the changes in price ratios were so small compared with those in quantity ratios (Chart 21). On closer examination, however, it is clear that the

⁴⁸ Although a large proportion of agricultural imports are considered by the Department of Agriculture to be "complementary."

TRENDS IN VALUES AND QUANTITIES

changes were definitely inverse. A period of comparative stability, until about 1886, was followed by a drop in the price ratio and a sharp increase in the quantity ratio. From 1898 to 1910 there was another period of stability for both, followed by another drop in price and jump in the quantity ratio. Only the very great rise in the quantity ratio between

CHART 20
Ratio of Agricultural Export to Import

(1913 ratio = 100)

Source: Appendix Tables H-20 and G-16.

1894 and 1898 seems eccentric; it might have been a product of the sharp increase in tariffs that took place at that time.

A surprisingly high elasticity of substitution between exports and imports of manufactures is implied by the fact that quantity-ratio fluctuations

CHART 21

Ratio of Manufactured Export to Import
Price and Quantity Indexes
(1913 ratio = 100)

Source: Appendix Tables H-20 and G-16.

TRENDS IN VALUES AND QUANTITIES

were so much larger than price-ratio movements.⁴¹ If our data had ended with the interwar period, the negative price-quantity relation might be attributed to a spurious correlation between two series with trends in opposite directions. But the reversal of the price-ratio trend after 1950—the rise in manufactured export prices relative to import prices—was accompanied by a great relative increase in imports of manufactures. This fact suggests that the large implied response of quantity to price ratios may have been quite genuine.

COMPARISON OF U.S. AND FOREIGN PRICES AND QUANTITIES

The rise in world trade of a new country, a new commodity, or a new supplier of a commodity is often accompanied by declining prices and terms of trade. We might think of the lowering of price as the way in which the newcomer forces its way into world markets. Or, perhaps more appropriately for a competitive economy, we might say that technological advances or the opening of new lands to cultivation have, by reducing prices, pushed the new country or commodity into world trade.

This phenomenon has often been noted in such cases as the growth of American raw cotton and British cotton goods exports in the first half of the nineteenth century, and in the rise of the American provision trade in the second half. The inverse movement of the volume of British exports with the terms of trade was commented on by Schlote,⁴² for example, and we noted (in Chapter 1) the relative fall in American export prices and terms of trade as the United States overtook and passed Great Britain as an exporter.

For the years covered by our new indexes it is possible to examine the behavior of some components of the major import and export classes. A few of many possible comparisons for the period before World War I are discussed below.

American exports of manufactures have been the main force behind the rise in this country's foreign trade since the 1890's. If we compare U.S. export prices and quantities with those of Great Britain (Chart 22), we note that both ratios were steady until the late 1880's. Between the 1890's and 1913, the ratio of American to British prices fell by almost a third, while the quantity ratio increased almost four times. Two brief reversals of the

⁴¹ See, however, the substantial elasticities of substitution (of the order of $2\frac{1}{2}$ -3) between U.S. and U.K. exports of manufactures found in G. D. A. MacDougall, "British and American Exports: A Study Suggested by the Theory of Comparative Costs," *Economic Journal*, December 1951. Our "elasticity of substitution" here is a somewhat strange construction, since exports and imports of manufactures are sold in different markets.

⁴² Werner Schlote, *British Overseas Trade*, pp. 46-47.

TRENDS IN VALUES AND QUANTITIES

price ratio decline were reflected in interruptions of the rise in quantity ratios.

Similarly, U.S. import prices for manufactures declined relative to British export prices, even though Great Britain supplied an important part of U.S. manufactured imports. Unless British export prices of manufactures to the U.S. fell relative to those of exports to other countries,⁴³ this means that U.S. import prices from countries other than Great Britain fell by

CHART 22
Ratio of U.S. to U.K. Export and Import Price and Quantity
Indexes, Total Manufactures and Textiles
(1913 ratio = 100)

⁴³ Kindlberger's figures (*The Terms of Trade*, p. 33) do not suggest that they do. He gives export unit values indexes for total United Kingdom exports and exports to the U.S. for 1900/1876 and 1913/1900 which can be combined into the following indexes (1872 = 100) for the two main manufactured goods categories.

Exports To	Metals and Manufactures	Textiles
U.S.	133	72
World	130	74

TRENDS IN VALUES AND QUANTITIES

more, and probably substantially more, than the 15 per cent decline in total import prices.

A narrower comparison⁴⁴ can be made of British and American exports of textile products. Again the fall in relative prices for U.S. exports over the period as a whole was accompanied by a great relative expansion in exports (Chart 22). Short reversals of the fall in prices were clearly reflected in the quantities. Relative prices of American textile exports rose in 1881-83, 1885-89 and 1903-07; relative quantities fell in 1881-84, 1886-89 and 1902-07.⁴⁵

CHART 22 (Concluded)

57421.

Source: Appendix Tables H-21 and G-17.

⁴⁴ One of many possible such comparisons using the data in Appendixes A to C.

⁴⁵ A number of other comparisons could be made between groups of British and American exports, using the indexes of Schlote (*British Overseas Trade*) and A. G. Silverman ("Monthly Index Numbers of British Export and Import Prices, 1880-1913," *Review of Economic Statistics*, August 1930). Textiles could be subdivided further, and comparisons might also be made of groups of metal products. The range of comparison could be widened a great deal by using domestic price data for narrow classes of commodities and both price and unit-value data for individual commodities.

TRENDS IN VALUES AND QUANTITIES

These observations on American import and export prices of manufactures cast further doubt on the representativeness of British export prices of manufactured goods. By showing the decline in Great Britain's share in world trade, the quantity trends illustrated here, as well as those shown by Hilgerdt,⁴⁶ reinforce the impression that British export prices of manufactures must have been rising relative to those of other countries. Thus, the improvement in Great Britain's terms of trade before World War I may have been more a reflection of the decline in the competitive position of her exports than a source of increasing real income.

The use of U.K. data to represent the whole world results in errors, which can be seen when the League of Nations indexes for U.S. manufactured exports and imports are compared with the NBER indexes (Table 8). The League's export-quantity index for 1881-85, derived by dividing U.S. export values by a price index constructed from U.K. data, was more than 40 per cent higher than the NBER index. On the import side the League's index falls by 11 per cent between 1881-85 and 1896-1900, while the NBER import-quantity index rises by over 30 per cent.

SIGNIFICANCE OF PRICE-QUANTITY RELATIONS

We have discussed a number of cases in which price and quantity changes showed a strong negative correlation. The direction of the relation is in

⁴⁶ *Industrialization and Foreign Trade*, pp. 157-158. Because of Hilgerdt's method of estimating quantity, these are essentially value trends.

accord with the hypothesis that the changes represent shifts in supply functions. However, two questions arise. Should it be possible to observe the effects of supply changes through price changes? And why are these price-quantity relations often characteristic of commodity aggregates even when not of the individual commodities?

If product *A* exported by country *X* is a perfect substitute for product *A* exported by country *Y*, their prices in country *Z* must, by definition, be equal. If there are no transportation costs, the export unit values for commodity *A* from the two countries will be equal also. An increase in productivity in country *X*, which results in a fall in the export price of commodity *A*, will cause a fall in the export price of *A* from country *Y*, if *Y* is to remain in the market. No interrelations between price and quantity changes will be observable.⁴⁷

What then accounts for the many negative price-quantity relationships that were found? It is the incomplete adjustment of prices in the two countries, because of such factors as transportation costs and imperfect substitutability. If transportation costs are introduced in the example above, the fall in *X*'s export price of *A* will widen *X*'s market area and contract *Y*'s market area. After the adjustment they will still be selling at the same c.i.f. price in any market they share, but *Y*'s export price need not have fallen to the same degree as *X*'s price.

Imperfect substitutability operates in the same manner. The fall in *X*'s price of commodity *A*₁ will drive *Y*'s exports of *A*₂ out of some uses or reduce its share in some areas, but will not eliminate it completely. One can therefore observe a fall in *X*'s export price relative to *Y*'s associated with a rise in *X*'s relative quantity of exports.

Even where there are no frictions (and every decline in *X*'s export price for *A* is matched by *Y*, but accompanied by a decline in *Y*'s volume of exports) a negative price-quantity relation may be observed for commodity aggregates or total trade. *A* will gain in importance among *X*'s exports and lose in importance among *Y*'s exports. In a price index which reflects this shift, the price of *X*'s exports will decline relative to that of *Y*'s exports. The quantity index of country *X* will rise correspondingly.

We conclude, then, that these negative price-quantity relations are not freaks or accidents. While they may not directly measure elasticities of substitution, they reflect them and may serve as approximations to them.

⁴⁷ Several attempts were made in the early stages of this study to explain the growth of particular U.S. food exports in terms of changes in export price relations between the U.S. and foreign competitors. Most of them failed because of the similarity between U.S. and foreign price movements.

Summary of Main Findings

Before going into some of the more technical aspects of the NBER indexes, it may be worthwhile to recapitulate the main findings of the first two chapters

Two widely held beliefs regarding net barter terms of trade found no confirmation in the data for the United States. One is that there has been a substantial long-term improvement in the terms of trade of developed countries, including the United States, the other, that there has been a significant long term deterioration in the terms of trade of primary as compared to manufactured products.

Although there have been very large swings in U.S. terms of trade since 1879, no long run trend has emerged. The average level of U.S. terms of trade since World War II has been almost the same as before World War I. However, the terms of trade have been improving quite steadily since 1951.

The preponderance of our data appeared to be contrary to the accepted view regarding the terms of trade between primary and manufactured products. Manufactured products in U.S. trade became cheaper relative to primary products, particularly before World War I. The purchasing power of U.S. manufactured exports fell with respect to both exports and imports of primary products, export prices of primary products rose compared with those of imported manufactures.

Neither of these findings prove that less developed or primary producing countries have experienced favorable shifts in their terms of trade. Like most of the original evidence on this question, ours is indirect. A regional or country breakdown of trade would be required to ascertain the course of U.S. terms of trade vis-a-vis particular areas or countries.

For only one of the comparisons of agricultural and manufactured prices—that within exports—was it possible to test roughly whether the trend represented mainly productivity or real income changes. It appeared that most of the long-run relative decline in export prices of manufactures could be accounted for by the fact that manufacturing productivity advanced at a more rapid rate than agricultural productivity, particularly before World War I. The reversal of the productivity relation since World War II has been accompanied by a reversal of the price relation as well. However, it was evident that the price ratio understated the plight of the agricultural sectors in the 1930's. By comparison with manufactured exports, agricultural exports suffered a drop in purchasing power per unit of input not only back to the prewar level, as indicated by the price ratio, but far below any level we have observed here.

The productivity data suggest that declining long-run net barter terms of trade are far from a certain sign of declining real income—they may well represent growing productivity and competitiveness. This impression is confirmed by the frequency with which declines in relative prices are associated with growth in relative quantities. This negative price-quantity relation appeared not only between agricultural and manufactured exports but between agricultural and manufactured imports, between exports and imports of agricultural products, and between exports and imports of manufactures. Similarly, the growth of U.S. exports of manufactured products (for example, textiles) relative to those of the U.K. was accompanied by a relative decline in U.S. export prices. These events, in conjunction with other evidence that negative relations between price and quantity changes are quite pervasive, suggest that productivity changes were the most frequent cause of long-term relative price movements.

A comparison of the value of exports and imports with the value of domestic output confirmed the view that there has been a decline in the ratio of trade to output. Import ratios have been falling for more than a century, while export ratios reached something of a peak in the last half of the nineteenth century before receding.

The volume of trade, however, shows no such long-run decline in importance. Recent export ratios have been among the highest since 1879; import ratios, very low just after World War II, have recently recovered strongly, reaching the pre-World War I levels in 1958-60. However, they have not repeated the higher levels of the interwar years.

The contrasting behavior of current- and constant-dollar trade ratios, caused by the substantial decline in the ratio of export and import prices to domestic prices, demonstrates how misleading the common practice of using them interchangeably can be. Most of the decline in this ratio occurred during the interwar period. The subsequent recovery in foreign trade prices fell far short of restoring the prewar relations.

Although no long-term trend was observed in aggregate trade-output ratios, there was evidence of a connection between export ratios and rates of growth in output for the agricultural sector, as well as for agricultural products individually. It took the form of a peak in the importance of the foreign market when the growth rate of domestic output was at its highest. Foreign markets took large shares of additions to output, even for commodities in which their initial share was not so great. In such commodities as cotton, grains, and meats it appeared that the wide extent and penetrability of the foreign market was a prerequisite for the rapid growth of

TRENDS IN VALUES AND QUANTITIES

American agriculture, particularly in view of the presumably low elasticity of demand for agricultural products. American economic growth was thus aided not only by the frequently cited size of the domestic market but by the opportunity the foreign market provided for rapid expansions in specialized fields of production.

CHAPTER 3

NBER Indexes: Methods of Construction and Comparisons Among Them

CHAPTERS 1 and 2 summarize long-term trends in the foreign trade of the United States as they are described by the new NBER indexes in conjunction with data previously available for later years. The remaining chapters deal mainly with the NBER indexes themselves, and thus with the period they cover : 1879 to 1923. The process of studying the technical characteristics of the indexes uncovers additional substantive findings relevant to the earlier chapters.

How the NBER Indexes Were Constructed

The NBER price and quantity indexes used in Chapters 1 and 2 are Fisher "ideal" index numbers. Paasche and Laspeyres indexes, employed later in this chapter, were an intermediate product in the computation of the Fisher indexes.

All the indexes were constructed in four segments : 1913-23, 1899-1913, 1889-99, and 1879-89, using the final year of each as the base. The segments were then linked at the overlapping years. The use of a single base for a period of ten or fifteen years has great computational advantages over annual linking, and also simplifies the interpretation of changes extending over several years. While avoiding the arbitrary character of bases far removed from the period studied, it does introduce into year-to-year comparisons some elements extraneous to the years compared.

A change in the price of an article which is of negligible importance in both of two years being compared could cause a substantial change in the Laspeyres index if the article were important in the base year. The Paasche index comparing two years can change even when all individual prices have remained the same, if the importance of the commodities has altered. Neither of these somewhat odd phenomena could occur in a direct comparison between two years.¹

¹ In a direct comparison between years 1 and 2 the Laspeyres price index is $\frac{\sum P_2 Q_1}{\sum P_1 Q_1}$. In an indirect comparison of years 1 and 2 with year 0 as a base, the Laspeyres index is $\frac{\sum P_2 Q_0}{\sum P_1 Q_0}$. The Paasche index under indirect comparison, is

$$\frac{\sum P_2 Q_2}{\sum P_0 Q_2} \bigg/ \frac{\sum P_1 Q_1}{\sum P_0 Q_1} \left(\text{or } \frac{\sum P_2 Q_2}{\sum P_1 Q_1} \bigg/ \frac{\sum P_0 Q_2}{\sum P_0 Q_1} \right),$$

instead of, as in direct comparison,

$$\frac{\sum P_2 Q_2}{\sum P_1 Q_2} \left(\text{or } \frac{\sum P_2 Q_2}{\sum P_1 Q_1} \bigg/ \frac{\sum P_1 Q_2}{\sum P_1 Q_1} \right)$$

Comparison of years from different segments is conceptually quite complicated, since it involves different sets of base year weights. It may be thought of as implying the assumption that the index for one period, if extended, would be roughly parallel to the index of the adjoining period.

The main advantage of the backward looking character of the index—the property that the base is the final year of a period rather than the initial year—is that it permits the fullest use of the steadily increasing detail in which trade data were published. In the first quarter of 1879, for example, there were slightly over 200 import commodities and 230 export commodities listed in the official trade returns, in 1923 there were more than 800 import and 1200 export commodities.

Indexes constructed with the terminal year instead of the initial year as the base have a number of peculiarities which must be kept in mind when the different types of indexes are compared. For example, the substitution effects which are expected on theoretical grounds (price and quantity changes negatively correlated), will cause our Paasche price indexes to rise relative to the Laspeyres indexes, the opposite of the usual case with initial year weights. On the other hand, where quantity and price changes are positively correlated, the Laspeyres price index will rise in comparison with the Paasche, again the reverse of the results with initial year weights.²

The commodity classification used here is the result of compromise among several objectives—comparability with other indexes, the isolation of economically significant classes of commodities, and reliability.

We constructed the classification to fit, with the proper combining of indexes, into the classifications used by the U.S. Department of Commerce. Thus, none of our minor groups were entered in more than one of the five economic classes or the eleven commodity groups of the Department of Commerce.³ The distinction between agricultural and nonagri-

² This is the phenomenon of "weight bias." Mills suggests that it is characteristic of short and medium periods, including business cycles, while the substitution relationship may prevail over long periods (Frederick C. Mills, *Statistical Methods*, 3rd Ed., New York, 1955, p. 452 n). It is, of course, the substitution relationship that is familiar from theoretical discussions of index numbers assuming constant tastes.

We could interpret these phenomena in another way. Substitution relationships are more likely to be observed when supply conditions are changing rapidly and demand is relatively stable, and weight bias when demand is shifting more rapidly (the 1913-23 period for many commodities).

³ The five economic classes are crude materials, crude foodstuffs, manufactured foodstuffs and beverages, semimanufactures, and finished manufactures. The eleven commodity groups are animals and animal products, edible, animals and animal products, inedible, vegetable food products and beverages, vegetable products, inedible except fibers and wood, textile fibers and manufactures, wood and paper, nonmetallic minerals, metals and manufactures, except machinery and vehicles, machinery and

cultural products was also maintained. Classes were set up for groups that seemed interesting from an economic point of view, or that demanded separate treatment on sampling grounds. The latter groups would otherwise have been combined with others exhibiting substantially different price behavior. The separation of such groups both improves estimates of the price behavior of larger classes, and narrows the margins of doubt surrounding these estimates (see Chapter 5). The next step was the selection of "covered" commodities—those for which unit values were accepted as representing prices or for which price data could be obtained from other sources.⁴ The other commodities are referred to as "uncovered."

The list of covered commodities rarely remained constant throughout a period. It was therefore often necessary for the index computation to have several base-year value totals [$\Sigma P_0 Q_0$ (covered items)], each comparable in commodity composition to a different segment of the period.

When the selections had been made and matching base-year values computed, Paasche, Laspeyres, and Fisher "ideal" price indexes were calculated for the covered items in each minor class.

Following this, value indexes were calculated for each minor class, encompassing both covered and uncovered items. These indexes compare the total value of all commodities in the class with the base-year value for the same commodities. As was true of the covered items, the total list of commodities in a class changed during a period, mainly because items disappear from the published listing as one goes back in time. Such items were assumed to fall into the catchall class "all other articles."⁵ As a result of these shifts, several base-year values— $\Sigma P_0 Q_0$ (All items)—often were required for a minor-class value index, as well as for the price index.

Quantity indexes for minor groups were computed by dividing value indexes by the Fisher price indexes. The assumption underlying this operation was that changes in the prices of items not covered were parallel to those of covered items.⁶

vehicles; chemicals and related products; miscellaneous. See U.S. Department of Commerce, Bureau of the Census: *Schedule A, Statistical Classification of Commodities Imported into the United States*, January 1, 1954, pp. VII and XVII and *Schedule B, Statistical Classification of Domestic and Foreign Commodities Exported from the United States*, Part II, January 1, 1949, pp. XXIV and XXVII.

⁴ The selection of covered commodities and the use of outside price data are discussed in Chapter 4.

⁵ Sometimes a commodity disappeared by merger with another. In most such cases we placed them both in the same class during that period to minimize shifts in composition within periods.

⁶ This is identical to the "coverage adjustment" used, for example, in Solomon Fabricant, *The Output of Manufacturing Industries, 1899-1937*, New York, NBER, 1940. See *ibid.* pp. 362-372 and Chapter 5, below, for a justification of this procedure in terms of the sampling assumptions used.

Price indexes for larger groups (the intermediate classes of Appendix B) were computed from data for the minor classes, giving each class the weight of both its covered and uncovered commodities. In effect, each minor class was treated as a commodity, with $\Sigma P_i Q_i$ (All items) as its $P_i Q_i$, and $\Sigma P_i Q_i$ (All items) as its $P_i Q_i$. The $P_i Q_i$'s were calculated by multiplying $P_i Q_i$'s by the Laspeyres price indexes, and $P_i Q_i$'s were calculated by dividing $P_i Q_i$'s by the Paasche price indexes. Those minor classes for which price indexes were computed were considered "covered" classes, analogous to covered items within minor classes. The calculated cross-products were summed across the minor classes to give the price and quantity indexes for intermediate classes, and these, in turn, were used to build the indexes for major classes and total exports and imports.

The base year dates were selected on a number of grounds. The final year of the study—1923—was selected as the base year for the last period, because we felt that Cowden's indexes for exports⁷ and an interpolation of the annual Department of Commerce series for imports could adequately fill the gap between that date and the beginning of the quarterly Department of Commerce series in 1929. The year 1913, the last year unaffected by the beginning of the European war, has been used as a base for many other prewar series. The years 1899 and 1889 which divided up the remaining period fairly evenly, were United States Census years, and therefore convenient for comparisons with domestic data.

Some other characteristics of the base years may be of interest. Three of them—1923, 1913, and 1899—are peak years in the NBER business cycle chronology, while the fourth, 1889, is roughly midway between a trough in April 1888 and a peak in July 1890. Against the more specific background of trade fluctuations, 1923 comes just after the trough in exports and imports following World War I, but is considerably above 1913. The latter comes at the end of a period of rising values, prices, and quantities for both imports and exports. The two decades from 1879 to 1899 mark something of an interruption in the very great rise in import and export values which characterized the post-Civil War period as a whole—an interruption resulting from a combination of increasing quantities and declining prices. The base year 1899 is situated just after the upturn in prices and import values, but several years after the upturn in export values. For import quantities, 1899 is in the middle of a fairly steady increase which covered the whole period 1879-1913, for export quantities it follows a period of very rapid growth and precedes a decade of retardation.

⁷ Dudley J. Cowden, *Measures of Exports of the United States*, New York, Columbia University Press, 1931.

Comparison of Paasche and Laspeyres Indexes

The Paasche and Laspeyres indexes shown in Appendix A are of interest for two reasons. One is that they show the range of error arising from the comparison of our Fisher indexes with Paasche and Laspeyres price and quantity indexes from other sources. The second, discussed later in this chapter, is that the differences between the two types of indexes shed some light on relations between price and quantity changes.

Many series with which one might compare export or import prices (such as the GNP deflator, the wholesale price index, and most foreign indexes) are Paasche or Laspeyres price indexes. It is not immediately clear, therefore, to what extent the apparent differences between the U.S. indexes and other series, such as those discussed in Chapter 1, represent real divergences in behavior or only the results of comparing dissimilar types of index numbers. The computation of Paasche and Laspeyres indexes permitted us to judge, in any specific case, whether the latter was the case, and to note that fact in the text. Even where no specific comparisons are made, the extent of Paasche-Laspeyres differences indicates whether any relations found are strong enough to make this type of "formula error" unimportant.

Ratios of Paasche to Laspeyres indexes, which measure the percentage differences between them, fluctuated much more violently between 1913 and 1923 than before, according to the data for agricultural products, nonagricultural products, and the five Department of Commerce economic classes (Table 9). In ten out of sixteen cases the swings were wider in those ten years than in the previous thirty-four. All the cases in which the range was over 21 per cent occurred in the later period.

The most spectacular range was in manufactured goods exports, where the Paasche index reached a level 50 per cent higher than the Laspeyres in 1916 (on a 1913 base). Most of this great discrepancy can be traced to manufactured chemical products (Export Class 075 in Appendix C), in which the Paasche index soared to twice the Laspeyres in 1916 and remained almost as high in 1917. Within this class the responsibility can be placed on one commodity: smokeless and other powder (item 6 in class 075). Its price rose much more than the average for all chemicals, while the value of its exports, less than one million dollars in 1913 and 1923, reached 262 million in 1916 and 338 million in 1917.

This one commodity was thus of negligible importance in the 1913-23 comparison and in the Laspeyres index for 1916 (weighted by 1923 values), but was of overwhelming importance in the Paasche index for 1916. Its

NBER INDEXES

influence in total manufactured exports was reinforced by the weight of exports of fuses and explosive shells and projectiles (items 25, 26, and 28 in class 075), which were uncovered commodities in the same class. They amounted to only \$652,000 in 1913 and \$663,000 in 1923, but reached \$394 million in 1916 and \$256 million in 1917.

SOURCE: Tables A-20-A-23

* Numbers following class titles are NBER major class designations as shown in Table A-30.

Because of the growth of these commodities, manufactured chemicals accounted for over a third of the total weight of covered classes in "manufactured products of mineral origin and rubber" (Export Class 147 in Appendix B) in 1916 and over 30 per cent in 1917, as compared with roughly 4 per cent in 1913 and 4½ per cent in 1923. The wide fluctuations in the Paasche-Laspeyres ratio, illustrated by this extreme case, are the direct result of wartime changes. At no other time does an insignificant commodity become a staple of international trade in a few months.

The Paasche-Laspeyres ratios were higher in 1923 than in 1879 for every major export and import class, for all but two of forty-five classes, they were higher in 1913 than in 1879 and higher in 1923 than in 1913 (Table 10). The only exceptions in the prewar period were two closely related export classes—agricultural products (Class 209) and products of

animal or vegetable origin, except printed matter and rubber products (Class 210). The two exceptions in 1913-23 were Import Classes 203 and 204 (manufactured foods, including and excluding tobacco products).

Column 3 of Table 10 shows how different the changes in price would appear if measured by a Paasche instead of a Laspeyres index.⁸ The Paasche index always shows a larger change, ranging from 2.7 per cent greater for Import Class 203 (manufactured foodstuffs) to more than 40 per cent for Import Class 202 (crude foodstuffs, including tobacco products).

Differences between Paasche and Laspeyres indexes not only shed light on the range of possible "errors" in comparisons of one type of index with another, but provide economic information as well. Both indexes are averages of identical price relatives for individual commodities, differing only in the weights they assign to each. In the Laspeyres indexes the price relatives are weighted by base-year values—those of the last year of each period in our indexes. (Alternatively, one could say that the prices are weighted by base-year quantities.) In the Paasche indexes each price relative is weighted by P_0Q_1 , the base-year price multiplied by the given (earlier) year quantity; each price is weighted by the given-year quantity. The Paasche index thus gives more weight than the Laspeyres to those commodities which have declined in quantity relative to the average—those for which Q_1/Q_0 was greater than the average.

What does this difference in weighting imply as to the meaning of discrepancies between the two indexes?⁹ Suppose, for example, that the Laspeyres index for a class is higher than the Paasche. Since the base year in our indexes is at the end, this means that the Laspeyres index has declined relative to the Paasche. It follows that the base-year weights were heavier than given-year weights for those commodities with the highest P_1/P_0 —those for which prices fell the most or rose the least. There was a shift in quantity terms toward those commodities that fell relatively in price.¹⁰ If, on the other hand, the Paasche index is higher, the base-year weights were lower for commodities with high P_1/P_0 , that is, there was a shift in quantity terms toward those commodities that rose most in price or fell least.

It is clear, then, that a higher (relatively falling) Laspeyres index suggests that substitution (or changes in supply conditions) was of predomi-

⁸ The Fisher index is of course closer to each of them than they are to each other.

⁹ It is simplest, in this connection, to think in terms of the original indexes for the four periods prior to linking.

¹⁰ This does not imply a shift in value terms. Evidence of such a shift could be found by comparing the Laspeyres index to an index with given-year value weights.

CONSTRUCTION AND COMPARISONS

nant importance, while the higher Paasche index implies that changes on the demand side were a stronger influence.¹¹

The difference between these indexes and conventional formulations (with the base year at the beginning) should be kept in mind. In both cases a higher Laspeyres index implies substitution in response to relative price changes. But in our indexes, $\text{Laspeyres} > \text{Paasche}$ means that the Laspeyres index is declining relative to the Paasche, while in the usual formulation, the reverse is true.

The interpretation of the Paasche-Laspeyres ratios is more complicated when the indexes are placed on a 1913 base by linking (Tables 9 and 10). For example, in the 1913-23 period the shifting of the base to 1913 transforms the situation as follows.

The interpretation must be reversed : the higher Paasche index implies substitution and the higher Laspeyres index, changes in demand. A preferable procedure is to concentrate attention on changes in the Paasche-Laspeyres ratio between any year and its matching base year. A relatively declining Laspeyres index, or a rising Paasche-Laspeyres ratio, implies shifts toward commodities becoming relatively cheaper. A decreasing ratio implies a shift in the opposite direction.

These relationships suggest that the upward drift of the Paasche-Laspeyres ratios, evident in most of the series (Table 10), is the result of substitution in favor of commodities with relatively falling prices. Although, strictly speaking, each year can be compared only with the base year of its period, a steady drift in the ratio can be identified with a gradual change in composition.

Several of the exceptions to the upward trend are associated with changes in demand. Most of the substantial declines in the Paasche-Laspeyres ratio occurred between 1916-18 and the 1923 base year (see basic tables, Appendix A). This means that high relative prices in 1916-18

¹¹ The observed price predominance does not necessarily imply a larger shift in the schedule, since the slopes of the supply and demand curves also influence the direction of the price-quantity relation.

were positively correlated with high relative quantities, many of the highest wartime prices were for those commodities (for example, gun powder) which experienced spectacular increases in demand

The cause of the downward trend in the Paasche-Laspeyres ratio for agricultural exports before 1913 is less clear. The relative increase in tobacco exports may be responsible. Tobacco was one of the few commodities whose prices increased even between 1879 and 1899, and one of the few to show a strong positive correlation between price and quantity relatives. These relations, together with the rapidly increasing consumption per capita, particularly of cigarettes, suggest that there were large increases in demand for tobacco products. A similar explanation can account for the fall in the Paasche-Laspeyres ratio for imports of manufactured foodstuffs. Here the main influence was the relative growth of sugar imports in the face of relatively increasing prices.

One of the sharpest declines in the ratio occurred in exports of crude foodstuffs after 1880-81. The high level during the first three years was clearly a demand phenomenon, when "a failure during the years 1879, 1880, and 1881, of the cereal crops of Europe and most other countries of the world, with the exception of the United States—a failure for which, in respect to duration and extent, there has been no parallel in four centuries—occasioned a remarkable demand on the latter country for all the food products it could supply at extraordinary prices"¹²

The information on price-quantity relations provided by the NBER indexes can be put in more formal terms. The Paasche-Laspeyres ratio, since it involves the extent and direction of responses of quantity changes to price changes, could be expected to bear some relation to the covariance between the two. And, in fact, a weighted covariance can be calculated from the two indexes.

The weighted covariance between price and quantity relatives for any year "1" is

$$Cov_w = \sum \left[\frac{P_0 Q_0}{\Sigma P_0 Q_0} \left(\frac{P_1}{P_0} - \frac{\Sigma P_1 Q_0}{\Sigma P_0 Q_0} \right) \left(\frac{Q_1}{Q_0} - \frac{\Sigma P_0 Q_1}{\Sigma P_0 Q_0} \right) \right]$$

If we use the following abbreviations

Value index	$(\Sigma P_1 Q_1 / \Sigma P_0 Q_0)$	=	V
Laspeyres price index	$(\Sigma P_1 Q_0 / \Sigma P_0 Q_0)$	=	L_p
Laspeyres quantity index	$(\Sigma P_0 Q_1 / \Sigma P_0 Q_0)$	=	L_q
Paasche price index	$(\Sigma P_1 Q_1 / \Sigma P_1 Q_1)$	=	P_p
Paasche quantity index	$(\Sigma P_1 Q_1 / \Sigma P_1 Q_1)$	=	P_q

¹² David A. Wells, *Recent Economic Changes*, New York, 1890, p. 6

Then,

$$\begin{aligned} Cov_w &= \sum \left[\frac{P_0 Q_0}{\Sigma P_0 Q_0} \left(V - \frac{P_1}{P_0} L_q - \frac{Q_1}{Q_0} L_p + L_p L_q \right) \right] \\ &= V \sum \frac{P_0 Q_0}{\Sigma P_0 Q_0} - L_q \sum \frac{P_1 Q_0}{\Sigma P_0 Q_0} - L_p \sum \frac{P_0 Q_1}{\Sigma P_0 Q_0} + L_p L_q \sum \frac{P_0 Q_0}{\Sigma P_0 Q_0} \\ &= V - L_q L_p - L_p L_q + L_p L_q \end{aligned}$$

$$Cov_w = V - L_p L_q^{13} \text{ or } \Sigma P_1 Q_1 / \Sigma P_0 Q_0 - (\Sigma P_1 Q_0 / \Sigma P_0 Q_0)(\Sigma P_0 Q_1 / \Sigma P_0 Q_0)^{14}$$

The weighted covariance, then, is the value index minus the product of the Laspeyres price and quantity indexes. Since we do not list the Laspeyres quantity indexes in Appendix A, the covariances can be computed for the NBER indexes as $Cov_w = V(1 - L_p/P_p)$.

The covariances are related to the Paasche-Laspeyres ratios as follows:

$$\frac{P_p}{L_p} = \frac{V}{V - Cov_w}$$

We have not computed covariances for many of the classes in Appendix A. From the Paasche-Laspeyres ratios, it can be inferred that those for the major classes, at least, were almost all negative once the effect of linking to a 1913 base is removed. The covariances, in combination with the variances among price ratios calculated in Chapter 5 and Appendix E, permit one to estimate the slope of the relationship between price and quantity relatives, comparing each year with the corresponding base year. Thus

$$\text{Slope} = \frac{Cov_w}{\sigma_w}$$

where σ_w is the weighted variance of the price relatives.

To summarize, this chapter gives further evidence of the pervasiveness of negative relations between price and quantity changes. To the comparisons among countries and among major classes in Chapters 1 and 2, it adds indirectly derived information on price-quantity relations within

¹³ This expression is Irving Fisher's factor-reversal test. The Laspeyres index passes this test (the expression is equal to zero) only when the covariance of price and quantity relatives (weighted by base year values) is zero, that is, when there is no correlation between price and quantity changes.

¹⁴ A recent paper by Victor Zarnowitz, "Index Numbers and the Seasonality of Quantities and Prices," in *The Price Statistics of the Federal Government*, New York, NBER, 1961, points out that these relationships between the Paasche and Laspeyres price indexes and the covariance of price and quantity changes were originally derived by Ladislaus von Bortkiewicz in *Nordisk Statistisk Tidskrift*, II, 1922, pp. 374-379, and III, 1924, p. 218.

major classes. It suggests, furthermore, that these indirect methods, using the differences between Paasche and Laspeyres indexes, could reveal more information on these relationships within intermediate and minor classes, and could, in addition, be applied to problems outside the area of international trade wherever the two types of indexes are available.

CHAPTER 4

Characteristics of Basic Foreign Trade Data

Nature and Testing of Customs Data

THE raw materials for this study, as for almost all investigations into international commodity trade, are the official monthly, quarterly, and annual reports on foreign commerce published first by the Treasury Department and in later years by the Commerce Department.¹ These reports show the value of exports and imports under several hundred (thousands in recent years) commodity titles. For some of them, quantities (and therefore, by implication, unit values) are also given.

The need for quarterly series, particularly for business cycle analysis, led to our use of imperfectly matching concepts of imports and exports. Exports of domestic (rather than domestic and foreign) merchandise were used because they seemed more logically related to the development of the domestic economy and because the inclusion of re-exports would have necessitated an extensive additional compilation of data. However, the corresponding import concept, imports for consumption, could not be used because quarterly data were available only for general imports.²

The principal type of import valuation required by the customs regulations is foreign selling price (the actual transaction price or wholesale price) plus expenses necessary before shipment to the U.S. Exports are valued at American selling price plus freight and other expenses between the source and the border of the United States. For some import items other value concepts are used, such as the price of comparable merchandise produced in the United States ("American valuation") or foreign cost of production. It is clear that, despite the regulations, many exporters and importers make up their own valuation rules.³

These customs data, compiled from declarations filed by exporters and importers or their agents, have not generally received very high marks for

¹ A detailed list of these reports is given in Appendix C.

² General imports are those coming directly through customs from foreign countries plus those entering customs warehouses. They exclude imports withdrawn from customs warehouses for domestic use. Imports for consumption include the same directly imported goods, but exclude those going from foreign countries into customs warehouses, and include withdrawals from warehouses for domestic consumption. For more extended discussions see R. G. D. Allen and J. Edward Ely, *International Trade Statistics*, New York, 1953, pp. 44-50, and Lawrence F. Schmeckebier, *The Statistical Work of the National Government*, Baltimore, 1925, pp. 327-329.

³ For an extensive discussion of import valuation, see R. Elberton Smith, *Customs Valuation in the United States*, Chicago, 1948.

CHARACTERISTICS OF BASIC FOREIGN TRADE DATA

accuracy from scholars who have examined them closely. They are often prepared carelessly, especially for duty free goods. Where tariff questions do arise, there is often incentive for undervaluation or incorrect description of merchandise. Furthermore, requirements for valuation change from time to time, are often ambiguous, and in some cases differ among classes of commodities.

In the period covered by the NBER indexes, the effects of respondents' errors were compounded by the procedures of the collecting agencies. When these agencies fell behind on the processing of reports, shipments were sometimes entered in the data for the months in which they were processed rather than the month of entry into the country.⁴

The only study which examined in any detail the accuracy of traders' reports to the customs authorities was one published by the Department of Commerce in 1939.⁵ Values on more than 12,000 invoices, a sample of imports of nine commodities between 1913 and 1937, were compared with those of corresponding customs reports. In terms of numbers, the results were discouraging, 60 per cent of the entries were incorrect (by balance of payments standards, but not necessarily according to customs regulations) and another 20 per cent lacked data necessary for the comparison. The most frequent discrepancies involved transportation costs, the failure to include the cost of transport to the customs border of the exporting country, or the incorrect inclusion of the cost of ocean freight to the U.S. Other differences involved the inclusion in whiskey import values of taxes payable by British consumers but not paid by American importers.⁶

There is, however, a brighter side to the results of this study. The discrepancies, although frequent, were not usually very important in value terms. This was partly because positive and negative errors cancelled each other out to some extent. The net discrepancy was very important only in the case of whiskey (47.5 per cent); in all the other commodities it was below 5 per cent. It should be noted, however, that in all of the transactions in petroleum and most of those in bananas (both of which involved

⁴ Questions of the accuracy of the data are discussed in more detail in the following sources: Schmuckebier, *Statistical Work*, pp. 330-339, 305; Dudley J. Cowden, *Measures of Exports of the United States* (New York, 1931), pp. 18-21; Eliot G. Mears, "The Foreign Trade Statistics of the United States," *Journal of the American Statistical Association*, pp. 501-516; Frank R. Rutter, "Statistics of Imports and Exports," *Publications of the American Statistical Association*, March 1916, pp. 16-34; and Smith, *Customs Valuation*.

⁵ U.S. Bureau of Foreign and Domestic Commerce, *Merchandise Import Statistics in the Balance of International Payments* (Report on Office Project No. 365-97, 320 conducted under the auspices of the W.P.A.) mimeo, 1939.

⁶ This was correct according to customs regulations but did not, of course, represent purchase prices.

intracompany rather than real commercial transactions), as well as roughly a quarter of those in rubber, sugar, and whiskey, the information needed for assessing the reports was not available.

Although we are aware of the frequency of these errors, we are unable to measure their direction and importance and therefore cannot correct for them. We are, however, able to test the data indirectly by methods described later in this chapter.

The sources of error listed thus far are probably of secondary importance, since they are likely to be random in relation to price changes. The fundamental difficulty, even if all the declarations and compilations were made correctly, is that we are attempting to construct a price index without price data. The unit values used instead apply to commodities defined in terms of the requirements of tariff legislation. They usually lack the precise specification typical of price quotations.

Most of the commodity titles in the export and import classifications are broad enough to include items of widely varying unit value. Where this is true, we cannot be sure whether a change in the unit value represents a change in price or merely a shift in importance among the items included.⁷

It cannot be assumed that differences between the movements of unit values and those of prices are scattered randomly over the commodity universe. The downward bias caused by a shift to a lower grade of product (see footnote 7), probably occurs more frequently among crude products than among manufactured goods. It seems likely that an upward bias would be more frequent among manufactured goods, as consumers, with secularly rising incomes, shift toward higher-quality goods within, as well as between, commodity categories.⁸

The problem posed by heterogeneity within commodity titles is not

⁷ Crude petroleum exports illustrate this problem. Unit values fell by about 25 per cent between 1902 and 1923, while the export unit value of illuminating oil, the BLS price for "refined petroleum for export," and the BLS price for Pennsylvania crude petroleum all rose by 40 per cent or more. The divergent behavior of the crude oil unit value was due to a shift from high-grade, high-priced Pennsylvania crude to cheaper grades from other fields.

⁸ Several examples of striking changes in quality, perhaps associated more with fashion than with rising incomes, can be found among the commodities listed in imports for consumption. For example, in the narrowly defined category "ladies' or children's gloves, lamb or sheep, glacé finish, unlined," the unit value increased by 29 per cent from 1899 to 1913. But the increase was not a change in price. It was caused principally by a shift from short gloves (under 14 inches in length), whose unit value rose by 8 per cent, to much more expensive long gloves (over 17 inches in length), whose unit value fell by 16 per cent. The shift was even larger between 1899 and 1907, when total unit value rose by 77 per cent, while that for gloves 14 inches or shorter rose by only 12 per cent and that for gloves over 17 inches fell by 11 per cent.

movements of related price or unit value series. Groups in which such interpolations played an important part have been indicated in the appendixes. They cannot, of course, be used for quarterly analysis.

Comparison of Customs Data with Price Series

Throughout this study two types of data have been used as equivalents: foreign trade unit values for broadly defined commodities and domestic prices for narrowly defined commodities. Both have appeared in previous studies of export and import prices,¹¹ but there has been little discussion of their relationship or of the consequences of using one instead of the other.

We have made some crude tests of these data to answer two questions: (1) How well do price and unit-value data agree in the prices they report?, and (2) when they do agree on price levels, how close is their agreement on the dating of transactions? The second question is of interest partly because timing discrepancies between value and price data might produce spurious quantity movements and partly because a knowledge of possible leads and lags might aid in interpreting cyclical behavior. The answer to the first question provides information on the accuracy of the foreign trade indexes. Although neither type of data is wholly satisfactory (the customs data are not prices and the prices are not foreign trade data), we have assumed that where two such different kinds of information agree closely, the truth cannot be far away.

Fluctuations in Prices and Unit Values

The question of agreement between price and unit value records, aside from timing, is a complicated one. Our confidence in the usefulness of the unit values rests mainly on the general agreement of hundreds of pairs of price and unit value series charted against each other. On the other hand there were many instances of violent disagreement. Because the degree of agreement was the main criterion for accepting or rejecting the unit

¹¹ Kreps used import unit values to represent import prices and U.S. wholesale prices to represent export prices (Theodore J. Kreps, "Import and Export Prices in the United States and the Terms of International Trade, 1880-1914," *Quarterly Journal of Economics*, August 1962). The currently published indexes of the U.S. Department of Commerce rely completely on customs data, as do most of the indexes for European countries used by Kindleberger in *The Terms of Trade*, pp. 322-333. Silverman's index numbers for the U.K. were based almost entirely on domestic market prices (A. G. Silverman, "Monthly Index Numbers of British Export and Import Prices, 1880-1913," *Review of Economic Statistics*, August 1930), as were some indexes mentioned by Kindleberger.

CHARACTERISTICS OF BASIC FOREIGN TRADE DATA

values, formal comparisons are made here only for commodities whose unit values were not discarded.

There have been no comprehensive comparisons of the two types of data. Mitchell¹² did make one test in which he compared two indexes of British prices for the years 1871-1902. The indexes were arithmetic means of equally weighted price relatives, one set made up of export and import unit values and the other of Sauerbeck's market prices. He found that the unit values "pursue a more even course than market price series" and, in particular, that the market price series fell more steeply during the price decline from 1871-72 to the trough in 1897.

¹² Wesley C. Mitchell, *Index Numbers of Wholesale Prices in the United States and Foreign Countries*, BLS Bulletin No. 284, Washington D.C., 1921.

CHARACTERISTICS OF BASIC FOREIGN TRADE DATA

It is clear in Chart 23 that the two indexes agree quite closely, except in 1871-74, despite the fact that the set includes some pairs of prices and unit values (particularly coffee, tea, and bacon) so poorly matched that by our standards the unit values would have been discarded. There is very little indication that the market price index is more volatile than the unit value index except during the first few years.

The differences between the two indexes, taken as percentages of the

Sauerbeck, 'Movement of Wholesale Prices in Great Britain,' *Monthly Summary of Commerce and Finance of the United States*, Bureau of Statistics, U.S. Department of Commerce and Labor, June 1904, pp. 4686-4692; and *Journal of the (Royal) Statistical Society*, Vol. XLIX, 1886, pp. 642-647.

CHARACTERISTICS OF BASIC FOREIGN TRADE DATA

unit value index, are shown in Chart 24. It is clear again that they fall within a narrow range, except in 1871-74, particularly when the tea and coffee series are removed. No downward trend of the market price index relative to the unit value index is visible after the first three years.

A comparison by Kindleberger¹³ of postwar Swedish unit value and price indexes indicates some very wide discrepancies. The largest of these occurred in 1951, when the export price index was 27 per cent higher than the unit value index, even though "the indexes for Sweden based on price are weighted by the value of the commodities going into exports and imports." But this evidence is not as good as it appears: the price series is a Laspeyres index on a 1935 base, while the unit value series are Fisher "ideal" indexes on a 1948 base.¹⁴ It is not clear therefore, what is responsible for the differences between the two indexes, the type of data used, as Kindleberger implies, or divergent weights and index number formulas.

There are several possible measures of the degree of similarity between prices and unit values. The correlation coefficient and the associated standard error would, in their conventional form, give too favorable a picture of the degree of similarity. This is because the usual correlation equation includes both a slope and a y-intercept. The two types of data would be perfect substitutes only if the ratio between them were constant, that is, if the correlation equation passed through the origin.

One could compare the ratios of the two series with the base-year ratio (as the index number formally does). In other words, one could measure the scatter around a line passing through the origin with slope equal to the base year ratio. We have not used this measure because it gives no weight to intraperiod comparisons. For example, a price and a unit value series might be considered poorly matched even though they were identical in every year except the base.

Our method of examining the price/unit value relation was to fit to the two sets of data a line passing through the origin, that is, to study the scatter around a "best" estimate of the ratio between unit value and price. These lines were fitted to prices and unit values for eleven of the most important export commodities in the 1913-23 period.¹⁵

¹³ *Terms of Trade*, p. 318.

¹⁴ The Swedish indexes are described in United Nations, *Supplement to the Monthly Bulletin of Statistics*, 1954, pp. 114 and 140.

¹⁵ The unit values were: wheat grain, wheat flour, hams and shoulders, cured, lard, leaf tobacco, unmanufactured cotton, bituminous coal, gasoline, 1913-21, extrapolated to 1923 by gasoline, naphtha, and other light products, illuminating oil, and refined copper in ingots, bars, rods, or other forms. (For sources see Appendix C.)

The BLS price series were—wheat Cash, No. 2, red winter, Chicago, wheat flour

CHARACTERISTICS OF BASIC FOREIGN TRADE DATA

In nine of the eleven cases the relationship was close, the "explained variance," or r^2 , being over 92 per cent. For two commodities, bituminous coal and leaf tobacco, it was only 71 per cent and 21 per cent respectively. When 1920 was dropped from the coal series and 1920 and 1921 from the tobacco series, the figures rose to 88 and 62 per cent.

More relevant for our purposes than the proportion of variance explained, is the relative error involved in estimating unit values from prices. This is measured by comparing "unexplained variation" in unit values with the unit values themselves.

For eight of the eleven commodities the ratio of the standard error of estimate¹⁶ to the mean of the unit values was less than 8 per cent. The ratio for lubricating oil was 10.4 per cent; for bituminous coal, 24.8 per cent; and for leaf tobacco, 45.7 per cent. When 1920 was removed from the coal comparison and 1920 and 1921 from that for leaf tobacco, the figures became 12.9 per cent and 28.4 per cent.

The leaf tobacco unit value and price series were the only badly matched pair in the group, and even these two series were consistent before 1913. Because of the wide range of wartime price changes, both the level of r^2 and the unexplained variation in the 1919-23 period were probably greater than would have been obtained in earlier years. In a more tranquil period, an unchanging price might serve as an excellent approximation to a slightly fluctuating unit value even though the r^2 were 0.

The distribution of the deviations around average unit value/price ratios is of interest because it reveals the frequency with which these ratios differed substantially from their mean in this sample of commodities. Most of the large discrepancies were concentrated in bituminous coal and leaf tobacco (Table 11). Half the deviations in these commodities were greater than 15 per cent, as compared with one out of ninety-eight in other commodities.

Chart 25 shows the similarity in time pattern of the wide deviations in leaf tobacco and bituminous coal. These follow, in general, the movements of the unit value series themselves. This is particularly true around the peaks of the two series and is a reflection not only of differences in timing

standard patents, Minneapolis; hams: smoked, Chicago; Lard: prime contract, New York; tobacco: leaf, average warehouse sales, Kentucky; cotton: Middling upland, New York; bituminous coal: Pocahontas, f.o.b. Norfolk, Va.; gasoline: motor, New York; petroleum: refined, standard white, 110° fire test, New York; lubricating oil: paraffin, 903 gravity, New York; Copper: ingot, electrolytic, refinery. These were all taken from U.S. Department of Labor, *Wholesale Prices, 1890 to 1923*, BLS Bulletin No. 367, 1925, and earlier issues.

¹⁶ Allowing for the loss of only one degree of freedom in the fitting of the line because only one constant was used.

between prices and unit values but also of the fact that the unit values, contrary to expectations, fluctuate more violently and over a wider range than the prices. The average of all commodities other than bituminous coal and leaf tobacco, moving in a narrow range between 3 per cent below and 4 per cent above the mean, shows a time pattern quite similar to that of coal and tobacco. This is certainly not conclusive evidence, but it does suggest that, in these commodities too, unit values tend to be more volatile than prices.

Timing Differences between Prices and Unit Values

It has been suggested¹⁷ that unit values from customs reports might be expected to lag behind wholesale prices because of the lag between transactions and shipments. In order to judge whether this lag existed and, if so, how large it was, we made a number of tests on American data for the 1913-23 period, which contained several violent price fluctuations. Since timing was the question here rather than the quality of the data, we chose commodities for which the two sets of data were comparable—where the annual prices and unit values traced out similar paths. In each test we compared the dates of turning points for corresponding fluctuations in pairs of monthly price and unit value series. No minimum length or amplitude of fluctuation was imposed—only the condition that there should be matching turns in both series.

One test, based on seven export unit value series and their corresponding BLS wholesale prices, indicated that wholesale prices do tend to lead unit values (Table 12). Fifty-three of the matching turns were coincident, however, wholesale prices led in fifty of the remaining fifty-nine cases. Most

of these leads were quite short—forty six of the fifty were one or two months, the average lead for all turns was half a month. For those cases in which wholesale prices led, the average was a month and a half.¹⁸

The results of a similar test, comparing U.S. wholesale prices with import unit values, are given in Table 13. Unit values lag more consistently than for exports (sixty five of ninety-three turns) and by a longer interval—a month on the average. The average lead of wholesale prices, for those turns in which they do lead, is 1.78 months. Wholesale prices lead in a majority of turns for every commodity in the list except one. Furthermore, these leads are not only more frequent than in exports, they are longer on the average, there are thirteen leads of more than two months as compared to only four among exports.

On the assumption that monthly data reveal the true leads of wholesale prices, an experiment was conducted to determine the extent to which our consolidation of the data into quarters hides or exaggerates these leads. Imports were used rather than exports because they showed longer, and therefore more troublesome, leads. The results, in Table 14, indicate that one effect of the consolidation—as might be expected, is to convert many of the leads into coincident turns. There are thirty six in the quarterly data as compared with nineteen in the monthly data, despite the fact that there are fewer matching turns in the former. Those leads which still remain have increased in length because of the increase in the minimum size of lead, the average lead is now 1.20 months as compared with 1.01 in the monthly data. All but one of the leads in the quarterly data are one quarter, the average is 3.06 months.

Leads and coincidences are almost equally represented in the quarterly data, but the leads are more frequent in four of the six commodities. Except for silk and rubber, where three of four price lags were eliminated, the lags were not erased by the shift to quarterly data.

The turning points that appear in Table 13 differ from those in Table 14. Some were eliminated by averaging in the shift from monthly to quarterly data, almost all of these were coincidences or one month price leads. Other turns appearing in the quarterly series had not been identifiable in the more volatile monthly data. The effect of shifting from monthly to quarterly data on an identical set of turns is shown in Table 15 for sixty-eight matched turning points.

¹⁸ It would have been desirable to extend this analysis to manufactured goods, but because many of their prices are constant for several months at a time the selection of a monthly turning point is arbitrary and small leads and lags disappear. In addition manufactured-goods prices exhibit fewer and much milder fluctuations than prices of crude and semimanufactured products.

Average	1.20	1 19	68

SOURCE See notes to Table 13

The longer leads of wholesale prices were reduced, on the average, by the conversion. One month leads were stretched slightly, and coincidences and one month lags were turned into short leads. The longer lags, however, were extended. The conversion to quarterly data thus altered the distribution of leads and lags, but it had no effect on the average length.

The Combination of Price and Unit Value Data as a Source of Error

'Outside' prices may behave differently from unit values for a number of reasons. The domestic commodity might be very different from the export commodity, even though they travel under the same name, when the commodities are the same, market conditions might be such that domestic and export prices move differently, even if the price movements are similar, the domestic price might lead or lag behind the export price. Any of these phenomena could lead to misconceptions not only about prices but about the behavior of quantities as well, since quantities are not estimated independently of prices.

Table 16 and Chart 26 illustrate the effect of using an estimated price which is identical to the true one except that it leads the true price by one period.¹⁹ The distortion of the quantity series is marked, although the timing is not altered. The amplitude is doubled and artificial accelerations are introduced into both the expansion and the contraction.

The estimation and interpretation of price-quantity relations may also

¹⁹ Periods two through six in Table 11 may be viewed as a business cycle divided into five stages.

CHARACTERISTICS OF BASIC FOREIGN TRADE DATA

be affected by such errors. If, for example, a series of arbitrary numbers called "value" is divided by another arbitrary series called "price" to get "quantity," the price-quantity relation will not be random. Since prices and values are independent, high prices will tend to be associated with low quantities, and vice versa. The price elasticity will tend toward one, and the level of the correlation between price and quantity will depend on the relation between the variance in value and the variance in price. The larger the latter compared to the former the higher the price-quantity correlation will be.

In terms of the indexes calculated here, there is some possibility that a spurious negative price-quantity relation has been introduced or that a positive relation has been obscured by such errors. At least the direction of bias, if not the extent, is clear.

CHART 26

Effect on Estimated Quantities of Using Estimated Prices Leading Actual Prices by One Period

Source: Table 16.

CHARACTERISTICS OF BASIC FOREIGN TRADE DATA

TABLE 16

EFFECT ON ESTIMATED QUANTITIES OF USING ESTIMATED PRICES
LEADING ACTUAL PRICES BY ONE PERIOD

	Period						
	1	2	3	4	5	6	7
<i>Actual</i>							
Price	110	100	110	120	110	100	110
Quantity	110	100	110	120	110	100	110
Value	121	100	121	144	121	100	121
<i>Estimated from leading price series</i>							
Price	100	110	120	110	100	110	120
Quantity	121	91	101	131	121	91	101
Value	121	100	121	144	121	100	121

These difficulties, most evident where quantities are derived directly from values and prices, exist wherever there is a lack of independence between the estimation of price and that of quantity. For example, an output series that includes a coverage adjustment in which parallelism in the price movements of covered and uncovered items is assumed,²⁰ introduces an element of interdependence in price and quantity estimation. The same applies even to those of our series which are based on unit values. If a shift in quality has been mistaken for a change in the price of a commodity, a spurious quantity change in the opposite direction has been introduced.²¹

Conclusion

Despite the defects of customs unit values, we selected, through a number of tests, many which could properly be used as prices. In addition, price data from other sources were combined with customs data to improve coverage. The resulting series, therefore, are referred to as price, rather than unit value, indexes.

There is strong evidence for some lag of unit values behind prices. It is rarely more than a few months in monthly data, and in quarterly data, seldom more than one quarter. Although these lags are negligible for long-

²⁰ See, for example, Solomon Fabricant, *The Output of Manufacturing Industries 1899-1937*, New York, NBER, 1940, especially pp. 362-372.

²¹ In the example of the gloves mentioned earlier, acceptance of the change in unit value indicated in the totals for 1899 to 1907, +77 per cent, would have meant an estimated change in quantity of about +40 per cent. When the data are broken down by length of glove, the highest possible estimate of the increase in average unit value is about +10 per cent, and the lowest increase in quantity, more than 100 per cent.

CHARACTERISTICS OF BASIC FOREIGN TRADE DATA

term analysis, they may affect short-term comparisons of foreign trade prices with quantities or domestic prices.

Earlier studies indicating much greater sluggishness in unit values than in prices were examined and found to rest on weak foundations. A comparison of the two types of data in our period indicated little difference in most series. The differences that were observed pointed to the contrary finding : unit values may have been more volatile than prices.

CHAPTER 5

Sampling Characteristics and Accuracy of Index Numbers

Sampling Problems in the Construction of Price Indexes¹

QUESTIONS of sampling procedure almost always arise in the construction of price and other index numbers, but are rarely treated explicitly. They are, in fact, obscured by the use of index number terminology. Our consideration of sampling problems first arose in setting up standards for commodity classification. We also wished to say something about the accuracy of our indexes beyond the usual warnings that they must be used with care. Many of the decisions to be made in designing the indexes and the questions to be answered in appraising them were closely analogous to problems of sampling design and the measurement of sampling error. We have attempted, therefore, to translate our problems into a simplified sampling terminology.

A THEORETICAL DESCRIPTION OF SAMPLING FOR A PRICE INDEX

Suppose that, ignorant of the vast index number literature and unable to collect every price, one set out to measure the average change in prices between two dates.

The first procedure to come to mind might be to list all the commodities, choose from among them in some random fashion and strike an average of the price ratios, weighting them all equally. But this method is clearly unsatisfactory—the classification of commodities is arbitrary, and, there-

¹ The first part of this chapter is an expanded version of a paper on "Some Sampling Problems in the Construction of Price Indexes" read at the Annual Meeting of the American Statistical Association, December 1955. Several substantial discussions of this subject have since appeared, each treating it from a slightly different viewpoint and, in some cases, giving evidence that random sampling is a practical possibility. The following are some of the main contributions: Irma Adelman, "A New Approach to the Construction of Index Numbers," *The Review of Economics and Statistics*, August 1958; K. S. Banerjee, "Calculation of Sampling Errors for Index Numbers" *Sankhya*, January 1960, and "A Comment on the Sampling Aspects in the Construction of Index Numbers," *The Review of Economics and Statistics*, May 1960, two staff papers of the NBER. Price Statistics Review Committee. Philip J. McCarthy, "Sampling Considerations in the Construction of Price Indexes with Particular Reference to the United States Consumer Price Index," and Victor Zarnowitz, "Index Numbers and the Seasonality of Quantities and Prices," published in *The Price Statistics of the Federal Government*, New York, National Bureau of Economic Research, 1961.

fore, the frequency with which any group of commodities is represented in such a selection depends on the fineness with which the group has been broken down, rather than on its importance. Each commodity would have an equal chance of being represented, but not each dollar of trade. If each commodity is thought of as a cluster of transactions, this procedure is one in which samples of equal size are drawn from each commodity cluster, even though some clusters are much larger than others. The probability of inclusion in the sample for a given dollar of trade, as well as the sampling fraction, would be inversely proportional to the size of the cluster.

What is needed is a method by which we can dip at random into the stream of trade, giving each dollar of transactions an equal opportunity to be represented in the sample, and, therefore, giving each commodity or group of commodities representation in proportion to the value of its trade. This might be achieved if the number of times a commodity appeared on the list was proportional to its importance (as measured by base-year value, given-year value, or some combination of the two, the choice depending on the type of index number used). Such a method would be equivalent to choosing from a list of dollars of trade, rather than commodities, and it would give each dollar of trade an equal chance of inclusion.

Of course this would be even more impractical than our first list of commodities. The same results could be achieved by selecting commodities from the first list and then weighting each price ratio by the importance of the commodity it represents. If we assume that all of the price ratios for a given commodity are identical (or that the sample of dollars of trade in that commodity would give an unbiased estimate of the mean or index for that commodity), the weighting achieves the same result as taking equal sampling fractions for each commodity. The equality of sampling fractions insures equal probability of inclusion for each dollar of trade.

The size (or importance) measure can be easily described for the Paasche, Laspeyres, Marshall-Edgeworth, and several other indexes. In the case of the Laspeyres price index, for example, it is the base-year value of (trade or exports in) the commodity. For the Paasche index it is the base-year price multiplied by the quantity in the year being compared with the base year. And for the Marshall-Edgeworth index it is the average of the Paasche and Laspeyres weights. Each of these can be put in the form: $\text{index} = \sum ab$, where a is the weight, the ratio of the size (e.g., value) of the commodity to the total for all commodities, and b is the ratio of given-year price to base-year price. The Fisher index cannot be represented in

this way,² but its weights can be approximated by those of the Marshall Edgeworth index.

We have discussed, so far, only simple sampling procedure, but we know, from such studies as those of Mitchell and Mills,³ that prices can be divided into groups which show distinctly different cyclical or trend characteristics. For this reason, a stratified rather than a simple random sample would improve the accuracy of our estimate of the mean. We should distinguish, to cite Mitchell's classification, crude from manufactured, agricultural from nonagricultural, animal from vegetable and from mineral, and consumer from producer goods. It is advisable to make even finer distinctions if groups within these strata differ significantly in the characteristics which interest us.

Stratification involves breaking the universe into several subuniverses, sampling within each as before, and then giving each mean (that is, price index) the weight of the subuniverse, or stratum, to which it refers, instead of the weight of the commodities selected. Stratification will increase the precision of our estimate of the mean even if we take a proportional sample (which, on the average, produces the same sampling fractions as a simple random sample) by insuring the proper weight for each stratum in each sample, instead of only on the average among all samples. Stratification also opens another avenue towards increased precision: the more variable groups can be sampled more heavily than the less variable ones.

Proportionate sampling can be described as that in which $\frac{n_k}{\sum n_k} = \frac{N_k}{\sum N_k}$, where n_k is the number in the sample from a stratum and N_k is the total number in the stratum. Optimum sampling, cost factors aside, is such that $\frac{n_k}{\sum n_k} = \frac{N_k S_k}{\sum N_k S_k}$, where S_k is the standard deviation for the stratum.⁴ An optimum allocation shifts the sample from the less to the more variable strata.

ACTUAL SAMPLING PROCEDURES IN PRICE INDEX CONSTRUCTION

It is obvious that the preceding paragraphs are not a description of the way in which price indexes are presently computed. In particular, the

² The Fisher index is a square root and can therefore be irrational. But $\sum ab$ must be rational, because the a 's and b 's are fractions, and their products and the sums of their products must therefore be rational.

³ Wesley C. Mitchell, 'Index Numbers of Wholesale Prices in the United States and Foreign Countries,' *BLS Bulletin* 284, 1921, and Frederick C. Mills, *The Behavior of Prices*, New York, NBER, 1927.

⁴ Morris H. Hansen, William H. Hurwitz, and William G. Madow, *Sample Survey Methods and Theory*, New York, 1953, Vol. I, p. 209.

selection of prices for inclusion in the indexes is not made by random methods. Instead commodities are chosen to obtain the greatest coverage at the least cost. A selection may be made, for example, of a number of the most important items,⁵ or of those in which trade is greater than a given amount, or perhaps of a sufficient number of items to reach a specified portion of the total.

Such methods may rest on the assumption that the value of trade in a commodity is not correlated with price behavior. Unfortunately, this is not true. Most of the commodities of large value are crude or semimanufactured materials or foodstuffs. Commodity classes for manufactures tend to be relatively small.⁶ Since the price behavior of manufactured goods differs from that of foods and materials, selection by amount of trade tends to bias the index towards the behavior of crude products.

Random selection is hampered, even for those agencies which collect their own price data, by ignorance of those properties of the universe which would be needed to guide sampling procedure.⁷ For those working with already collected data such as foreign trade reports, the problem of nonresponse is the main obstacle. That is, for the great majority of commodities listed in the U.S. customs returns, either no data on quantities (and unit values) are given at all, or the commodity titles are amalgamated into groups so heterogeneous that the unit values cannot be treated as prices. Because most commodity categories give no information on price changes, index number compilers are often led to use whatever is available without worrying about possible biases.⁸

⁵ This was the case, for example, with the import and export price indexes computed by Theodore J. Kreps, "Import and Export Prices in the United States and the Terms of International Trade, 1880-1914" *Quarterly Journal of Economics* August 1926. The Department of Commerce indexes are described as including directly "all leading commodities for which quantities are available and which show a reasonable degree of homogeneity . . .," U.S. Department of Commerce, Bureau of Foreign and Domestic Commerce, *Foreign Trade of the United States, 1936-49*, GPO, 1951, note to Table 10, p. 6. See also Dorothy S. Brady and Abner Hurwitz, "Measuring Comparative Purchasing Power" *Problems in the International Comparison of Economic Accounts*, Studies in Income and Wealth, Volume Twenty, Princeton University Press for the NBER, 1957.

⁶ Since the commodity classification is arbitrary, these manufactured goods categories could be amalgamated into larger classes only at the cost of grouping together dissimilar articles. These groups would be so heterogeneous that changes in unit values could not be interpreted as price changes. Thus the selection problem would have been solved by producing what could be described in sampling terminology as a nonresponse problem. The large manufactured goods classes so created would not yield any meaningful price data. One reason for this difficulty is that in the manufacturing process a few types of raw cotton, for example, can be made into many types of cloth and these into uncountable varieties of clothing.

⁷ See Brady and Hurwitz in, *International Comparison of Economic Accounts*, pp. 310-311. Their discussion relates mainly to international comparisons of price levels, but could apply almost as well to comparisons over time.

⁸ See, however, the articles by Adelman, Banerjee, and McCarthy, referred to in Note 1.

SAMPLING CHARACTERISTICS

The problem of nonresponse would not be troublesome if it were spread evenly over the commodity universe. But we find differences in price behavior between manufactured goods and crude materials, and between goods whose method of production is changing technologically and those whose technology is stable. The former of each pair are likely to show high rates of nonresponse which threaten to bias the index.⁹

STRATIFICATION TO MINIMIZE SELECTION AND NONRESPONSE BIAS

The possibilities of bias inherent in nonrandom sampling methods and in extensive nonresponse cannot be eliminated completely, but we can attempt to minimize their effects. As in reducing sampling error, the method is to stratify the universe by those attributes of commodities which we know to be related to price behavior. In addition, stratification by attributes which are related to nonresponse or selection bias, would eliminate some bias due to differences in nonresponse among strata, although not bias due to within-strata differences.¹⁰

There is no way of being agnostic with regard to the price behavior of any commodity. If the stratification has any validity, every commodity should be placed within some stratum. Omitting a commodity from the price index is equivalent to assuming that its behavior is that of the average of all included commodities. It would be illogical, for example, to treat machinery, which we know to be a durable, nonagricultural, producers' good as behaving like the average of all commodities if we have a durable vs. nondurable or a producers' vs. consumers' or an agricultural vs. nonagricultural product classification which reveals significant differences in price behavior.

⁹ Some of these shortcomings in the BLS Wholesale Price Index of that period are discussed in Morris A. Copeland, *Some Suggestions for Improving our Information on Wholesale Commodity Prices*, and Robert W. Burgess, "The General Structure of Wholesale Prices," both in *Proceedings of the Ninety-second Annual Meeting of the American Statistical Association*, 1931.

¹⁰ The sampling problems involved in the construction of price indexes from data collected for other purposes are similar to those dealt with in Appendix G of *Statistical Problems of the Kinsley Report*, by William G. Cochran, Frederick Mosteller, and John W. Tukey (American Statistical Association, Washington, 1954). In both cases, the sample has not been drawn randomly, and it is therefore difficult to know exactly what the parent population is. The stratification described here is parallel, if it is performed after the sample has been drawn, to the process of "adjustment" of sample means described in that report. It can be thought of as a process by which the characteristics of the sample are compared with those of the population and the sample mean reweighted in accordance with the characteristics of the population. The constructor of price indexes has one advantage: there have been studies of the price universe which give some guidance as to which characteristics are significant for pre-sampling stratification or post-sampling adjustment.

AND ACCURACY OF INDEX NUMBERS

It would be ideal to design the stratification scheme in advance, using knowledge about the behavior of prices gained from other studies. Such a stratification would reveal many empty classes, classes containing only commodities for which we have no price data, and would illuminate the areas where bias is most likely. We have usually made the best guess possible by amalgamating many such classes with those which seemed most closely related.

THE MEASUREMENT OF THE PRECISION OF PRICE INDEXES

Published price indexes have rarely been accompanied by estimates of sampling error, but some independent estimates have been attempted. With the exception of those in the articles by Adelman and Banerjee mentioned earlier, they have probably exaggerated the accuracy of the indexes.

A. L. Bowley, in 1924¹¹ made some measurements of the sampling error of Sauerbeck's index, published in the *Statist.* His method indicated coefficients of variations (standard error ÷ mean), of 1.6 to 3.4 per cent for the 1899-1913 period (forty "independent" price series), and 4.6 to 6.0 per cent for the 1913, 1919-22 period (thirty-nine "independent" price series).¹² Frederick C. Mills¹³ made more extensive investigations of this subject, estimating coefficients of variation for eight of his own index numbers. The coefficients for the fixed-base indexes, which were in every case larger than those for the corresponding link relatives, had the following ranges :

	1891-1913	1914-26
Unweighted arithmetic mean	.8-2.1	.7-4.7
Unweighted geometric mean	.8-1.8	.6-1.8
Weighted arithmetic mean	1.4-3.4	.9-3.0
Weighted geometric mean	1.4-3.4	1.0-3.1

If the confidence interval is measured by twice the coefficient of variation, these figures indicate ranges of error of 3 to 12 per cent for the *Statist* index. For the Mills indexes, the ranges are 1.5 to 7 per cent in the prewar period and 1.2 to 9.5 per cent in the later years (even though the series covers 200 to 400 commodities).

¹¹ *Relative Changes in Price and Other Index-Numbers*. London and Cambridge Economic Service, Special Memorandum No. 5, Feb. 1924, pp. 6-8.

¹² Bowley computed probable errors of the means for only one year. We extended the computation to the remaining years using his method and his data, and increased the probable errors by 50 per cent to approximate standard errors.

¹³ *Behavior of Prices*, pp. 240-274.

Fisher did not publish any extensive calculations on actual index numbers, although he recognized the existence of sampling problems. For a 200-commodity index he compiled from *Dun's Review*, he suggested a probable error of 1.5 per cent,¹⁴ which would imply a standard error of slightly over 2 per cent. Mudgett¹⁵ presents the formulas for the standard error of the mean (i.e., the index), both weighted and unweighted, with and without the finite sampling correction, and for stratified as well as unstratified sampling. He points out that stratification can be effective in reducing the sampling variability of the average, but he does not discuss its use to minimize the effects of bias in selection.¹⁶ He is therefore led to say of the BLS Wholesale Price Index, which has for some years contained over 800 items, "It might even be possible to say that such a comprehensive index is practically devoid of sampling error."¹⁷ Since Mudgett mentions the total number of items, it would appear that for this purpose he is treating the BLS index as if it were constructed from a simple random sample.

STRATIFICATION AND THE MEASUREMENT OF SAMPLING ERROR

We suspect that most of the preceding estimates of sampling error are too low because they assume simple random sampling, and, therefore, probability of representation proportional to size. In fact, there are serious differences in representation, and the groups which are poorly represented are not necessarily those with low dispersion.¹⁸ The total number of items included in an index is clearly not significant without some information about the distribution (consider, for example, a 100 item index where ninety-eight of the items were drawn from one identifiable half of the population and only two from the other).

The error caused by combining in the same stratum groups which differ in the extent of coverage (or nonresponse) can be illustrated by the following example. Suppose that we can stratify a population into two groups that are equal in size (N_1) but differ in the extent of coverage (or probability of inclusion in the sample). Let us say that they differ to the extent that the number of commodities in the sample from one group (Kn_1) is K times the number from the other group (n_1).

¹⁴ Irving Fisher, *The Making of Index Numbers*, Boston, 1922, p. 340.

¹⁵ Bruce D. Mudgett, *Index Numbers*, New York, 1951, pp. 51-54.

¹⁶ Mudgett does observe that it is often exceedingly difficult to draw a random sample.

Ibid., p. 53.

¹⁷ *Ibid.*, p. 54.

¹⁸ It might be that the poorly covered groups, since they are frequently manufactured products, have a large proportion of sticky prices and therefore small dispersion of price changes over short periods. But this would not be likely for price trends over longer periods.

The variance of the sample mean (σ_x^2) from a stratified sample can be written as $\frac{1}{N^2} \sum \left[N_h^2 \frac{S_h^2}{n_h} \right]$ where $N = \sum N_h$ and S_h^2 is the variance within a stratum.¹⁹ In our example, with the two strata described above, this variance (σ_x^2) becomes

$$\frac{1}{(2N_h)^2} \left[N_h^2 \frac{S_h^2}{n_h} + N_h^2 \frac{S_h^2}{Kn_h} \right]$$

which reduces to $\frac{S_h^2}{n_h} \cdot \frac{1+K}{4K}$.

But suppose we had combined these two strata into a single one and had treated the stratified sample as if it were a simple random sample. Our estimate of the variance of the mean would have been $\frac{S^2}{n}$ where

$$S^2 = \frac{n_h S_h^2 + Kn_h S_h^2}{n_h + Kn_h} \text{ and } n = n_h + Kn_h$$

This estimate of the variance reduces to $\frac{S_h^2}{n_h} \cdot \frac{1}{1+K}$. The ratio of the first, correct, estimate of the variance of the mean to the second, incorrect, one is $\frac{(1+K)^2}{4K}$. Or, in other words, the valid estimate of the standard error of the mean (or index) would be $\frac{K+1}{2\sqrt{K}}$ times the estimate derived by treating the sample as random, as was done by Bowley and Mills and, implicitly, by some of the others mentioned above.

For small values of K the understatement of the standard error is not large; at $K=2$ it is about 6 per cent. It rises to 14 per cent for $K=3$, 20 per cent for $K=4$, and 40 per cent for $K=9$.

This ratio would be higher if it took into account the case where n in one stratum is so small that it should be treated as a small sample.

Thus another important reason for stratification emerges: without it we cannot make any reasonable estimate of the sampling error of the index. It is true that the stratification which would be optimum for increasing the precision of the estimate of the mean and for reducing bias in that estimate (one based on homogeneity with respect to the mean, or price behaviour) would not be the optimum stratification for estimating the sampling error of the mean. The latter would be one which revealed the greatest differences in coverage (probability of inclusion) among strata;

¹⁹ Hansen, Hurwitz, and Madow, *Sample Survey Methods*, p. 189.

SAMPLING CHARACTERISTICS

that is, which grouped together types of commodities whose degree of coverage was similar. But a detailed stratification for the former purpose is likely to reveal many of the differences in coverage relevant to the latter.

MEASURES OF VARIABILITY AND SAMPLING ERROR IN THE NBER INDEXES

We have performed measurements of variability and sampling error in two ways. The first is appropriate when a weighted index is used to deflate the value of the uncovered items. It treats the covered items as if they had actually been picked with probability proportional to size. In other words, it assumes that the commodity distribution of the covered items is representative of the uncovered ones as well—that a large item represents a greater number of observations of the mean than a small one. The variance and other measures (Appendix Tables E-1 through E-3) are computed by weighting each price ratio by the size of the commodity.

There are certainly grounds for uneasiness about this method of estimation, since we are not sure of the representativeness of the sample. If, for example, the covered items in a class are dominated by a single large item which is not outstandingly important among the uncovered commodities, we are likely to have underestimated the margins of error. This danger is increased by the fact that we assume no within-commodity variance even though we know there must be some.

For these reasons, we computed, as a rough check, a second estimate of the standard error which treats each commodity, regardless of size, as a single observation. The standard error is thus estimated from an unweighted variance of the price ratios. Only the first step in these computations, the calculation of unweighted standard deviations, is shown here (Table E-1), but the relation between unweighted and weighted standard errors can be inferred from this table. The counterpart of this assumption in the index computations would be the deflation of the uncovered items by an unweighted rather than a weighted index of the covered items.

It would be possible to find from such computations that the margins of error surrounding the indexes were tolerably small even where only a small fraction of all the items were sampled, provided we were willing to assume the randomness of the sampling, and had sufficiently large numbers of items included. However, given our assumption that the covered items are free from sampling variation, these measurements exaggerate the range of error, for sampling error applies only to that part of each class which consists of uncovered items. To estimate the variability of the whole group we made a finite sampling adjustment, multiplying the variance of

the mean by one minus the coverage ratio. These computations yield the adjusted measures in Appendix Tables E-2 and E-3.

The coverage ratio itself is often used as a measure of the reliability of an index.²⁰ The usual practice is to set a minimum level of coverage below which an index is considered too unreliable for use.²¹ The logic of this criterion is that, given the degree of variation among the covered items, the standard error of the index varies directly with the noncoverage ratio.

Measures of sampling error take account of both the coverage ratio and the variability of the covered items. Thus a maximum level of error, rather than minimum coverage which is only a proxy for it, can be established as a criterion for acceptance of the index.²² One index with a fairly low coverage may be acceptable if the price behavior is homogeneous and there are many items, while another with higher coverage may be rejected because it contains heterogeneous price behavior and few items.

Table 17 summarizes the sampling error measurements for NBER minor classes. It is evident from the coefficients of variation how important the finite sampling (or coverage) adjustment is to the reliability of the indexes. The unadjusted coefficients were frequently quite high; almost a third of the export and half of the import classes which contained more than one covered commodity showed coefficients of more than 10 per cent, and more than one out of ten had coefficients above 20 per cent. These figures exclude, however, all the classes in which there is no variability (those consisting only of one commodity) and those in which variability is unknown because none or only one of the commodities is covered.

Once the coverage adjustment is made (Columns 2 and 4) the minor class indexes appear more reliable. Of the 120 cases where unadjusted coefficients were over 10 per cent, only eight of forty-six remain on the export side and sixteen of seventy-four on the import side. If completely covered one-commodity classes are included, approximately 40 per cent of all the coefficients are zero and over half are 2 per cent or less.

The sampling variability of the five major classes which correspond to

²⁰ For example, in John H. Adler, Eugene R. Schlesinger, and Evelyn Van Westerborg, *The Pattern of United States Import Trade Since 1923*, Federal Reserve Bank of New York, 1952; in descriptions of the official Department of Commerce quantity and unit value indexes for U.S. exports and imports; and in Solomon Fabricant, *The Output of Manufacturing Industries*, New York, NBER, 1940.

²¹ Fabricant, for example, did not accept indexes whose coverage was less than 40 per cent (*Ibid.*, pp. 34-35).

²² Fabricant in *Output of Manufacturing Industries*, pp. 362-367, presented some calculations showing the effects on his indexes of various degrees of divergence between the price movements of covered and uncovered items, but gave only very general indications of the likelihood of each degree of divergence.

SOURCE Appendix Table E-3

Commerce Department economic classes is summarized in Table 18 (and described in greater detail in Appendix Table E 4) Coefficients of variation for imports are larger than those for the corresponding export classes—sixteen out of twenty times The coefficients for finished manufactures are generally high, those for food classes are low, with the exception of Import Class 201 (crude foods) in 1899 The size of this coefficient is due mainly to one small minor class, Import Class 006 (spices), in which the three covered items were so divergent in behavior as to give a standard error of estimate of .44 before finite sampling adjustment and .23 even after coverage is taken into account

On the whole, the errors seem tolerable None of the coefficients of variation exceeds 3.5 per cent, none outside of manufactures is greater than 2.3 per cent Seventy per cent of the total and 80 per cent of those outside finished manufactures were under 2 per cent The coefficients are large enough, however, to suggest that it would be useful to experiment with random selection to produce more valid variability estimates

^a The classes included are those equivalent to the five Department of Commerce economic classes.

Extent of and Changes in Coverage

Coverage ratios are interesting not only as crude measures of accuracy but also because they reflect differences, between covered and uncovered items, in price behavior and in supply and demand elasticities. Although it is rarely possible to disentangle these factors, radical changes in coverage, when the commodity list is unchanged, are grounds for suspecting heterogeneity in a commodity class. This is especially true where the changes in the coverage ratios are correlated with changes in the price index; it would appear likely in such a case that the price changes in the covered items were not duplicated in the uncovered ones. This correlation is not conclusive evidence of divergences in price behavior, however. It could result from differences in elasticity of demand. Suppose, for example, a

SAMPLING CHARACTERISTICS

group in which covered and uncovered commodities were identical in price behavior but the former were subject to a much more elastic demand. Coverage would then decrease every time the group's prices rose and increase every time they fell. By the same reasoning we could say that differing elasticities could conceal the expected influence of differing price behavior on coverage ratios.

COVERAGE IN NUMBER FOREIGN TRADE INDEXES

Coverage ratios for minor classes are summarized in Table 19 below. There are almost 6,900 class years (numbers of classes multiplied by the number of years each is available) for which indexes might have been computed (over 5,500 indexes actually were calculated). Of the 6,900 class years over 40 per cent consisted almost completely (more than 95 per cent) of covered commodities, and could therefore be said to suffer from virtually no sampling error. At the other extreme, for over 19 per cent of the class years no coverage was possible or so little that no indexes were calculated. This group of empty classes was particularly important in the earliest period: 31 per cent for exports and 29 per cent for imports. Another 7.5 per cent of the class years are of marginal quality, with coverage of less than 50 per cent. Most of these, particularly in the lowest ranges, occur in periods in which the majority of years had adequate coverage.

In every period, the proportion of classes more than 95 per cent covered was slightly higher in exports than in imports. But the better coverage in exports disappears at a somewhat lower standard: imports show a higher proportion with coverage above 60 per cent, and a smaller proportion completely uncovered in every period.

Among those groups for which indexes were calculated, over half the class years had coverage ratios above 95 per cent. Exports had a higher proportion than imports in that class in every period, but even for imports, at least 45 per cent of the class years had coverage ratios over 95 per cent.

Measurements based on numbers of class years do not take into account differences in the importance of individual classes. They therefore present a very conservative assessment of the indexes, since many of the largest classes (for example, cotton, grain, and tobacco exports, and coffee, tea, cocoa, and sugar imports) consist entirely or almost entirely of covered items. Measured by number or value, the coverage ratios tend to be exaggerated in classes where prices were used in place of unit values. The price series describe narrowly defined commodities but are applied here to much

broader categories. For example, a BLS series on "Cattle, steers, good to choice," is used here to deflate values of an export commodity defined only as "cattle." The price series, therefore, apply only to a part of the export values, and an unknown part at that. It would be more appropriate (but much more laborious) to use a combination of several cattle series for the price index, attaching some measure of dispersion to it. Alternatively, one could count only part of the cattle series as contributing to the coverage in the class. Instead, as with the unit values, we assumed no variance within a commodity, and treated its whole value as a covered item.²³

With these limitations in mind we may examine the coverage ratios for total exports and imports which appear in Table 20. These ratios were computed only for the earliest year in each period and for the comparable base year figure. The earliest year of each period was used because it is generally the one with the poorest coverage.²⁴ For exports, coverage was above 85 per cent in each of the four periods, and for imports it fell no lower than 72 per cent.²⁵ Coverage of exports was highest in the earlier years and then declined as the improvement in commodity detail and in the availability of price data was offset by the decline in the importance of agricultural commodities for which both price and unit value data were plentiful. In the case of imports the shift in composition away from manufactured goods and the improvement in data led to a slight increase in coverage.

²³ This difficulty is involved in the problem of estimating from "composite commodities" discussed by Banerjee, *Calculation of Sampling Errors for Index Numbers*.

²⁴ This may seem puzzling in view of the fact that the base year coverage shown in Table 20 is generally worse than that for the earliest year. Coverage is shown for a list of commodities that is unchanged during a period, and thus no advantage is taken of the availability of more data in later years. It is true that those commodities which were covered in 1879 for example, were a larger proportion of the total then than they were ten years later. But the commodities covered in 1888 were usually a larger proportion of the total in 1889 than were those covered in 1879. In other words, total coverage increased through time but the importance of the group of commodities covered initially usually decreased.

²⁵ Coverage of the Department of Commerce import indexes has been close to 70 per cent except for a fall to 60-65 per cent in 1957-59. That of the export indexes was 55-67 per cent before World War II. Since then it has ranged between 35 to 50 per cent, averaging about 45 per cent (U.S. Department of Commerce, *Business Statistics, 1957 Biennial Edition*, p. 251, and later editions). The Federal Reserve Bank indexes covered 64 to 69 per cent of the value of imports (Federal Reserve Bank of New York, *The Pattern of United States Import Trade Since 1923*, by John H. Adler, Eugene R. Schlesinger, and Evelyn Van Westerborg, May 1952, p. 64). The degree of coverage in Fabricant's output indexes ranged from 52 to 70 per cent of total value added (Solomon Fabricant, *The Output of Manufacturing Industries*, p. 602).

AND ACCURACY OF INDEX NUMBERS

Imports	81.8	76.0	72.7	78.6	68.8	71.7	70.4	74.7

Appendix Tables E-5 to E-8 show intermediate and major class coverage ratios for the earliest year and the base year of each period. The base year coverage ratios shown include only those commodities covered in the earliest year. It is clear that the covered items are unevenly spread over the commodity universe. In exports, for example, the first twelve major classes, including all foods, crude materials, and agricultural exports, do not show a single case of coverage below 90 per cent. Import coverage was somewhat lower, but the first nine classes, consisting of foods and other agricultural products, included no cases under 86 per cent.

No major export class had less than 50 per cent coverage, and of those with between 50 and 70 per cent, twenty-six of twenty-seven cases were in classes 214, 215, 221, and 222.²⁶ One important component of all of these was Export Class 146 (manufactured metal products, including machinery and vehicles), whose coverage ranged between 33 and 66 per cent, mostly below 50 per cent. Among the 372 intermediate export classes listed in Table E-5, only eighteen had coverage ratios below 50 per cent (eleven among manufactured metal products) and nine others between 50 and 60 per cent.

Major import classes were more sparsely covered. There were thirteen cases below 50 per cent (as against none for exports) and nineteen between 50 and 60 per cent. But here again they were concentrated in the same area: thirty of thirty-two were in five classes.²⁷ Only once did coverage dip even slightly below 40 per cent.

The main sources of this poor import coverage are Import Class 150 (*manufactured products of mineral origin*) and its component, Import Class 147 (manufactured metal products), both of which contain very few covered items. Almost all the coverage of manufactured imports is in textiles and wood and paper products (Import Classes 064, 066, and 126).

²⁶ Manufactures, including tobacco products; manufactures, excluding tobacco products; mineral products; and nonagricultural products.

²⁷ (1) Nonagricultural products; (2) products of mineral origin; and (3) three classes of manufactured products.

Changes in the coverage ratios are of interest because they can suggest some inferences about the price behavior of uncovered items. They do this by virtue of the fact that they measure the relative rates of growth in value of covered and uncovered commodities. Where coverage is rising the covered commodities are growing more rapidly.

Especially among exports, relative value changes for major classes of commodities have tended to move in the opposite direction from relative price changes. Groups whose prices have fallen relatively have tended to gain in importance, for example, manufactured products in general and automobiles in particular. If this relationship is typical we can use these changes in coverage to draw some inferences as to the probable direction of bias in our indexes.

Some change in coverage arises from shifts in the importance of classes. For example, as we have seen, the rise within exports of the lightly covered manufactured goods class tended to lower total coverage. This change in coverage does not imply bias, it is taken account of in the construction of the index, as are any such changes arising from shifts in importance among minor classes. Shifts in importance within minor classes might suggest bias, however, because the method of constructing the indexes assumes that within each minor class prices of uncovered commodities move with those of covered commodities.

We therefore ask the following question: How does the value of covered commodities at the end of each period compare with what it would have been if the coverage in each minor class had remained constant at the earliest year's level? If actual coverage is greater, we know that covered commodities have increased in value more rapidly, if it is smaller, the uncovered items have been growing more rapidly.

Tables E 9 to E 12 show, for each intermediate and major class, actual coverage at the end of each period as a per cent of that which would have existed if there had been no changes within minor classes during the period. For total imports and total exports actual coverage is less than expected in three out of four periods, but never by more than 5 per cent. More significant lags in the growth of covered items appear among the major classes. In four major export classes, all among manufactures, non-agricultural products, and products of mineral origin, coverage within minor classes fell by more than 10 per cent. These classes, which fell in price and increased in value relative to other exports, show evidence of upward bias in the price index. That is, there is some ground for suspicion that their prices fell even more, relative to those of other classes, than is revealed by our indexes. The loss in coverage in these classes was concen-

trated particularly in Export Class 146 (manufactured metal products), and its main component, Export Class 143 (manufactured iron and steel products). These lost close to 50 per cent of their coverage over the four periods.

Changes in coverage among major import classes were much more scattered. There were six instances in which the growth of covered items exceeded that of uncovered items by more than 10 per cent and three over 20 per cent. (Only once did an export class show the value of covered items gaining on that of uncovered items by more than 4 per cent during one period.) All of these were among manufactured goods imports, as were three cases in which covered items fell behind by more than 20 per cent. The very low coverage in these classes left room for large increases and decreases, but in contrast to the situation on the export side, the net change in coverage was very close to zero.

Comparison of NBER Indexes with Others

U.S. Department of Commerce Indexes

SINCE the NBER and Department of Commerce indexes have been combined to obtain the long series used in Appendix A and Chapters 1 and 2, it is of interest to check their consistency for the years in which they overlap, 1913 and 1919-23. Perfect agreement between the indexes could not be expected, even though both are Fisher "ideal" indexes. The Commerce series were computed with annual linking, each year serving as the base for the following year, while the NBER indexes use 1923 as a base for all the years compared. Furthermore, the value series are slightly different—we have attempted to use the 1949 classification of commodities throughout, and shown overlaps wherever there are changes in the composition of a class, while the Commerce Department used the contemporary classification and ignored small changes in composition. In addition, there are differences in weighting—the Department of Commerce in its computations, moves directly from individual commodities to its five economic classes, the NBER indexes are built up from individual commodities through minor and intermediate classes to major groups, in an attempt to give each class, rather than just each commodity, its proper weight.

Despite all these possible sources of disagreement the two indexes match very well in most years—so well that they could hardly be distinguished on a chart. We therefore compare them, in Table 21, by examining the ratios of the Commerce to the NBER series, year by year and for the period as a whole. Between 1913 and 1923 the Commerce indexes for total exports and imports increased slightly faster than our own. The ratio of 1923 to 1913 was 3 per cent greater in the Commerce series for imports and only 0.3 per cent for exports. In none of the year-to-year indexes for the totals was the divergence more than 5 per cent.

Among the ten comparisons for economic classes (five import and five export) there were three cases where the ratio of the Commerce to the NBER index increased by 6 to 7 per cent over the period as a whole. Among the fifty year-to-year comparisons there were three where the difference was greater than 10 per cent. One of these three was imports of manufactured foods, 1920/1919, for which the Commerce index was 207.8 and our index 184.8. The most important commodity in this class was cane sugar, weighted in the Commerce index¹ at 78 to 93 per cent. This is

¹ Unpublished details of the commodity composition of the Department of Commerce indexes were supplied to us by Mr. Carl P. Blackwell, Director of the International Economic Analysis Division, Bureau of Foreign Commerce.

COMPARISON OF NBER INDEXES WITH OTHERS

considerably greater than its importance in the NBER index.² The role of sugar prices in the discrepancy between the indexes is confirmed by the fact that whenever the price relative for sugar was above the two indexes the Commerce index was higher; whenever it was below, the NBER index was higher.³

A similar case is the crude materials export index which contains the largest 1923/1913 discrepancy and the third largest year to year discrepancy. The commodity responsible is raw cotton, which Commerce weights 9 to 18 per cent more heavily than we do. Here again the Commerce index is higher when the cotton price relative is higher than the two indexes and lower when the cotton price is lower.

In both of these instances the greater number of commodities in the

Finished manufactures	96.8	100.6	102.3	99.2	104.7	103.5

SOURCES: Commerce indexes: U.S. Department of Commerce, *Foreign Trade of the United States, 1936-49*, International Trade Series No. 7, 1951, Table 10, p. 6 and Table 13, p. 9. NBER indexes: Appendix Tables A-1 and A-3.

² It is difficult to measure the weight of a single commodity in the NBER indexes. The weight of a commodity is amplified by the coverage adjustments as minor and intermediate classes are combined. But even if we estimate a maximum weight for sugar by adding the weight of all uncovered items in manufactured foods to that of sugar, clearly an overestimate, its weight in our index remains below that in the Commerce index. The greatest discrepancy is in the 1919/1913 comparison where the Commerce weight is more than 25 per cent larger than even our maximum.

³ The sugar price relative was never between the two indexes.

NBER sample as well as the method of weighting tend to reduce the importance of the single dominant commodity

The discrepancy for exports of manufactured products 1919/1913 the largest in Table 21 has a different origin the heavier weight in the NBER index of two groups with below average price increases These are vehicles with a lower price ratio in the NBER index as well as a greater weight (perhaps double)⁴ and machinery, heavily weighted in our index while virtually omitted from the Commerce series The machinery component of the NBER index was constructed entirely from outside price data

The measures listed in Table 21 might be said to understate the differences between the two series because they are comparisons of index numbers themselves rather than of changes in them In two classes the Commerce and NBER import price indexes moved in opposite directions in 1923 crude foods where NBER showed a decline of 0.2 per cent and Commerce a rise of 0.7 per cent and finished manufactures where the NBER index fell 1.1 per cent and the Commerce index rose 3.5 per cent.

In other instances the changes were much more divergent than the indexes themselves In 1923 again the ratio of export price indexes for finished manufactures was 96.1 per cent. But the Commerce price index fell by 4.5 per cent and the NBER index by only 0.6 per cent, the Commerce index thus declined by 7.5 times as much Another example not so dependent on the smallness of the denominator was in exports of crude materials in 1922 Here the Commerce index rose 25 per cent almost twice as much as ours

Kreps Indexes for Exports and Imports

The only comprehensive indexes duplicating the NBER series for an extended period are those compiled by Theodore J. Kreps⁵ These are annual Marshall Edgeworth price indexes for total exports and imports covering fiscal years 1879 through 1916 on a 1903-13 base Kreps used unit values as import prices and U.S. wholesale prices as export prices The import index included twenty-nine commodities covering 30 to 40 per cent of total imports the export index twenty-eight commodities covering 40 to 45 per cent of total exports

A comparison of the Kreps and NBER export price series (Chart 27)

⁴ Our index was constructed from price data instead of the unit values used in the Commerce index. By both measurements the price ratio for vehicles was very low

COMPARISON OF NBER INDEXES WITH OTHERS

CHART 27

U.S. Export and Import Price Indexes: Kreps and NBER, Fiscal Years
(calendar 1913 = 100)

Source: Appendix Table G-1.

COMPARISON OF NBER INDEXES WITH OTHERS

shows a fairly similar trend between 1880 and 1913 if only the first and last years are taken into account. But the Kreps index was generally below ours before 1900 and could be said to have shown some upward trend by comparison. In addition, its fluctuations were sharper, particularly the decline during the depression of the 1890's and the subsequent rise.

The import price series reveal larger disagreements, as high as 20 per cent or more compared with a maximum of 15 per cent between the two export series. As in exports, the divergences are concentrated in the period before 1900. But there is a somewhat stronger trend in the ratio of the Kreps index to ours—downward in the case of imports. The fluctuations in the Kreps index are more violent, particularly before 1900.

Since Kreps' export price index rose relative to ours, and his import index fell, the two indexes of the terms of trade of the United States

CHART 28
U.S. Terms of Trade Indexes (Exports — Imports),
Kreps and NBER, Fiscal Years
(calendar 1913 = 100)

Source Appendix Table H 2

COMPARISON OF NBER INDEXES WITH OTHERS

showed a greater divergence than either of the components. The disagreement is considerable; as can be seen in Chart 28, the Kreps index fell as far as 27 per cent below ours, on a 1913 base.

The Kreps indexes give a much more favorable picture of the development of the terms of trade, showing an improvement of almost a third between 1879 and 1913 instead of the 10 per cent indicated by the NBER indexes, and more than 40 per cent between 1894 and 1913 instead of less than 20. Furthermore, the NBER terms of trade series fluctuates less violently, even after 1900.

The distribution of weights among economic classes in the two indexes is compared in Table 22. Weights in the base period of the Kreps index, 1903-13, are compared with those of the 1899 base for the NBER index, and a similar comparison is made of 1892 weights for exports and 1890 weights for imports (these are the years in which the two indexes were furthest apart).

The main source of the differences in export indexes must have been the much heavier weighting of raw cotton by Kreps. This was a massive 42.7 per cent of the base-year weight of the Kreps index,⁶ and only between 15 and, at the very most, 25 per cent of the 1899 base in the NBER index.⁷

In 1892 the two sets of export weights show a large discrepancy only in one class, manufactured products, but the base-year data show that Kreps weighted both crude foodstuffs and manufactured products less than half as heavily as the NBER indexes and gave crude materials more than twice as much weight.

No single commodity stands out on the import side as did raw cotton among exports. The main differences are the much higher weights assigned by Kreps to crude foodstuffs and the much lower ones assigned to manufactured products. Prices for the latter group in our calculations were below the average of all other commodities relative to 1899 and considerably smoother in their fluctuations.

USDA Index of Agricultural Export Prices

The United States Department of Agriculture has published several indexes of agricultural export quantities and values. The one which best matches the NBER index is a Laspeyres quantity index on a fiscal 1909-14 base. We have converted it into a Paasche price index, for comparison with our series, by dividing it into the Agriculture Department's value series.

⁶ Given-year weights could be assumed to be more similar for the two series.

⁷ It was during the 1889-99 period that the greatest gaps between the two indexes appeared.

SOURCE Kreps figures from "Import and Export Prices"

Comparison with the NBER Fisher indexes reveals a remarkable similarity despite the use of different base years and index number formulas. When both indexes are placed on a 1913 base they never differ by as much as 10 per cent and, before World War I, only once by more than 5 per cent (Chart 29). The ratio of the USDA index to ours shows no trend. It is almost a straight line, but droops slightly at the ends. The 1899 to 1913 period, when the base periods for the two indexes are very close and fluctuations in the ratio are at a minimum, is also the one where the ratio is at its highest.

COMPARISON OF NBER INDEXES WITH OTHERS

Census Bureau Price Index for Foreign Agricultural Materials

The Bureau of the Census has published a Laspeyres index of US prices of foreign agricultural materials^a on a 1935 39 base, with US consumption rather than import weights. The prices are not import unit values.

CHART 30
Prices of Imported Agricultural Products NBER and
Bureau of the Census

COMPARISON OF NBER INDEXES WITH OTHERS

but are prices "quoted on organized exchanges or markets" at a stage representing "the first important commercial transaction in the commodity after arrival in this country."⁹

The NBER series closest in coverage to the Census index is Import Class 209 (agricultural products). This class is, however, more comprehensive than the Census series because it covers all agricultural products while the Census excludes those which are produced to a substantial extent in the United States, no matter how important they are among imports.

Discrepancies between the two indexes arise not only from differences in coverage, but from the Census Bureau's use of a later base period, consumption rather than import weights, and prices rather than unit values (this last is probably of little significance).

It is clear in Chart 30, that the discrepancies between the two series are very large. The Census index has a strong downward trend by comparison with the NBER series and, in the earlier part of the period, quite different fluctuations as well. After 1913 most of the difference between the two indexes can clearly be attributed to sugar which is the second most important commodity in the NBER index but is excluded from the Census index because it is considered a domestic agricultural product. Other, but less important, factors in these years are the lighter weight of silk and the absence of wool in the Census index. Both commodities rose in price faster than the average.

In the years before 1913 the fluctuations in the Census series follow those of rubber fairly closely, while the NBER index does not. That is because the weight of rubber in the Census index is almost three times that in ours. The falling trend of the Census index relative to our own can be explained mainly by the absence from it of wool prices, which rose sharply. The Census Bureau considered wool, like sugar, a domestic agricultural product.

APPENDIXES

Appendix A

Indexes and Values for Total Exports and Imports and Major Classes, 1879-1960

This appendix includes the following two sets of data :

(1) Tables A-14 through A-29 (basic tables) present price and quantity indexes and values for the period 1879-1923 for the NBER major classes. These data provide information on total exports (Export Class 220) and total imports (Import Class 221), on the five major economic classes into which the Department of Commerce divides foreign trade, and on selected combinations and variations of them.

Annual Fisher price and quantity indexes and dollar values are presented for all of the 22 export classes and 23 import classes. In addition, for 12 selected major classes, the basic tables include annual Paasche and Laspeyres price indexes, quarterly Fisher price and quantity indexes, and quarterly dollar values. (See Table A-30.)

(2) In Tables A-1 through A-11 the NBER data for 1879-1923 are combined with statistics of the Department of Commerce and the Department of Agriculture to extend certain series forward to 1960 and several back to 1869. For the period 1879-1960, annual price and quantity indexes and dollar values are presented for total exports and imports, for the five major economic classes used by the Department of Commerce, and for agricultural products. The NBER major classes which are used for these breakdowns for the period 1879-1923 are indicated in the individual table notes.

The correspondence between the major economic classes of the Department of Commerce and the comparable NBER classes is not exact because of the way in which miscellaneous articles, not elsewhere specified, are handled. The Department of Commerce includes this group with manufactured products and its five groups therefore sum to the total. The NBER series, on the other hand, include these articles in the total, but they are not assigned to any of the five major economic classes. The difference in value figures for 1879-1923 between total exports or imports and the sum of the five economic classes is therefore attributable to these miscellaneous articles.

Certain adjustments in price and quantity indexes and in value figures have been incorporated in Tables A-1 through A-11, to take into account the change in the United States customs area in 1900. The specific adjust-

APPENDIX A

ments are indicated in the individual table notes. For a detailed explanation of the adjustments, see Appendix F.

Two additional tables are presented to show the classification scheme of exports and imports :

Tables A-12 and A-13 show the main components, by value, of the five major classes in the NBER series which correspond to the Department of Commerce economic classes.

Table A-30 shows, for each major class, the composition in terms of intermediate, minor or other major classes.

1954	261.6	203.9	276.4	268.9	288.6	224.4
1955	290.1	215.5	280.4	300.3	321.6	269.8
1956	315.0	227.1	292.2	318.7	327.4	327.8
1957	322.1	229.9	304.0	320.5	323.1	351.8
1958	334.6	231.8	365.6	297.6	321.7	396.5
1959	398.7	245.5	388.2	328.1	399.2	524.9
1960	384.2	237.7	386.2	305.2	366.2	523.5

NOTES TO TABLES A-1 THROUGH A-4

The NBER major classes which correspond to the economic classes used in these tables are as follows:

<i>Economic Class</i>	<i>NBER Export Class</i>	<i>NBER Import Class</i>
Total	220	221
Crude foods	201	201
Manufactured foods	203	203
Crude materials	212	212
Semimanufactures	213	213
Manufactured products	215	220

212 Crude materials, incl tobacco				608,262	1,404,090
024 Crude tobacco	85,358	160,467	236,840	36,321	57,158
026 Hides, leather and products, crude	3,615	13,774	11,790	105,893	118,917
029 Furs, unmanufactured	19,981	22,377	51,088	14,060	79,639
036 Rubber and related gums, crude				84,902	188,472
038 Oilerds, crude	8,200	12,503	34,397	10,322	65,475
045 Cotton, crude			6,608	19,400	49,443

051 Crude vegetable fibers, excl. cotton and jute	7,638	20,817	18,562	39,660	37,024
054 Wool, crude	10,788	18,696	11,660	28,776	129,711
057 Silk, crude	11,099	21,472	42,781	89,770	392,299
062 Wood and products, crude	6,188	9,908	8,087	25,778	40,219
069 Petroleum and related prods., crude				11,525	63,295
145 Crude metals		2,754	7,715	36,657	58,092
Total accounted for	67,509	122,301	192,688	503,164	1,279,744
213 Semimanufactured products					
027 Hides, leather and products, semimfd.	76,841	124,252	134,495	355,161	726,611
039 Veg. oils, expressed, and fats	5,377	5,864	5,751	9,292	16,742
063 Wood and products, excl. paper, semimfd.			3,472	17,694	50,228
065 Paper and related products, semimfd.	4,633	10,330	9,260	22,726	70,684
073 Precious stones	4,982	13,559	16,135	15,936	74,401
078 Nonferrous metals, semimfd.	5,207	10,516	32,889	33,931	68,117
081 Iron and steel products, semimfd.	26,195	31,795	8,814	107,946	172,182
086 Semimfd. chemicals	24,803	29,663	35,950	14,576	26,215
123 Semimfd. fibers		9,007	7,494	85,381	111,273
Total accounted for	71,197	110,734	119,765	24,538	65,101
				332,020	654,943
220 Manuf. products, incl. tobacco and art works					
147 Manuf. metal products	135,591	205,283	167,838	373,547	724,000
064 Wood and products, excl. paper	8,860	13,457	9,302	31,194	58,255
066 Paper and products, manufactured				9,920	28,973
076 Manuf. of stone, glass, and clay				25,191	125,038
088 Miscellaneous	10,260	14,861	13,171	18,690	45,904
089 Art works				23,599	53,389
126 Manufactured fibers	96,956	142,512	108,553	35,054	29,496
Total accounted for	116,076	170,830	131,026	196,043	318,234
				339,691	659,289

TABLE A-30
COMPOSITION OF MAJOR CLASSES

Major Class	Major, Intermediate, and Minor Class Composition
A EXPORTS	
201 ^a Crude foodstuffs, excluding tobacco	101 ^b -102
202 Crude foodstuffs, including tobacco	101 ^b and 103
203 ^a Manufactured foodstuffs, excluding tobacco	108 and 111 ^b
204 Manufactured foodstuffs, including tobacco	108 and 112
205 ^a Agricultural foodstuffs, excluding tobacco	104 and 113
206 Agricultural foodstuffs, including tobacco	103 and 113
207 ^a Foodstuffs, excluding tobacco and products	201 and 203
208 Foodstuffs, including tobacco and products	202 and 204
209 ^a Agricultural products	206, 132, and 041
210 Products of animal or vegetable origin, excluding printed matter and rubber products	208, 135, and 041
211 Crude materials, excluding tobacco	129 and 144
212 ^a Crude materials, including tobacco	130 and 144
213 ^a Semimanufactured products	1899-1923 131 and 145 1895-98 131, 058, 060, 141, 063 ^c , and 074 ^c 1882-94 131, 060, 141, 063 ^c , and 074 ^c 1879-81 131, 141, 063 ^c , and 074 ^c
214 Manufactured products, excluding tobacco manufactures	041, 137, and 147
215 ^a Manufactured products, including tobacco manufactures	214 and 026
216 Crude materials and semimanufactures, excluding tobacco	211 and 213
217 ^a Crude materials and semimanufactures, including tobacco	212-213
218 ^a Crude materials, semimanufactures and foods, including tobacco and products	208 and 216
219 Total exports, excluding "all other articles, n.e.s."	214 and 218
220 ^a Grand total	219 and "all other articles n.e.s."
221 Total products other than those of animal or vegetable origin	144-145, and 147
222 ^a Total nonagricultural products	002, 013, 020, 024, 137, 134, and 221

(continued)

TABLE A-30 (concluded)

Major Class	Major, Intermediate, and Minor Class Composition
B. IMPORTS	
201 ^a Crude foodstuffs, excluding tobacco	101 ^d and 104
202 Crude foodstuffs, including tobacco	101 ^d and 105
203 ^a Manufactured foodstuffs, excluding tobacco	108 and 111 ^d
204 Manufactured foodstuffs, including tobacco	108 and 112
205 ^a Agricultural foodstuffs, excluding tobacco	106 and 113
206 Agricultural foodstuffs, including tobacco	107 and 113
207 ^a Foodstuffs, excluding tobacco and products	201 and 203
208 Foodstuffs, including tobacco and products	202 and 204
209 ^a Agricultural products	206, 131, and 044
210 Products of animal or vegetable origin	208, 141, 139, and 044
211 Crude materials, excluding tobacco	136 and 148
212 ^a Crude materials, including tobacco	211 and 024
213 ^a Semimanufactured products	1879-1914: 033, 039, 138, and 149 1915-23: 033, 039, 042, 138, and 149
214 Crude materials and semimanufactured products	211 and 213
215 ^a Crude materials, including tobacco; and semi-manufactured products	214 and 024
216 ^a Crude materials, semimanufactured products, and foods, including tobacco and products	208 and 214
217 Manufactured products, excluding tobacco	1914-23: 044, 071 (excluding 1915-16), 076, 087, 091 (excluding 1914-15), 139, 082, 084, 079 ^c , 083 ^c , 088 ^c , 071 ^c (1915-16 only) 1889-1913: 044, 071 (1913 only), 076, 087, 139, 147, 088 ^c 1879-88: 044, 076, 139, 147, 087 ^c , 088 ^c
218 Manufactured products, including tobacco	217 and 025
219 Total, excluding "all other articles n.e.s." and art works	216-217
220 ^a Manufactured products, including tobacco products and art works	218 and 089 ^c
221 ^a Grand total	219 and "all other articles, n.e.s." and art works
222 Total products of mineral origin	148-150, 091 (1916-23 only)
223 ^a Total nonagricultural products	002, 013, 020 (excluding 1913-15), 022, 139, 140 and 222

^a Basic tables include annual Fisher price and quantity indexes and annual values. For classes noted, additional data are presented: annual Paasche and Laspeyres price indexes, quarterly Fisher price and quantity indexes, and quarterly values.

^b See notes for Export Classes 101 and 111, Appendix B.

^c These are uncovered classes.

^d See notes for Import Classes 101 and 111, Appendix B.

Appendix B

Indexes and Values for Intermediate Classes, 1879-1923

THIS appendix presents annual price and quantity indexes and values for selected intermediate classes. We list in Tables B-7 and B-8 the composition of all intermediate classes, the reader must refer to Appendix C for the commodity detail. In making up the intermediate classes, some uncovered minor classes were deflated by price indexes for specific covered classes rather than by the average of all covered minor classes within the intermediate class. We made the selection of these specific deflators by a comparison of the behavior of the price indexes during periods for which there was an overlap. For example, Export Class 037 was an uncovered class for 1879-88 and 1913-23. We found that during the period 1889-1912, when prices were available, they followed quite well the fluctuations of the index for Export Class 038. We therefore used the price indexes for 038 to deflate 037 during the 1879-88 and 1913-23 periods.

ANNUAL FISHER PRICE INDEXES,
SELECTED INTERMEDIATE EXPORT CLASSES
(1913=100)

TABLE B-7

LIST OF INTERMEDIATE EXPORT CLASSES

Export Class		Class Composition
CRUDE FOODS		
101	Animal	001-002 ^a
102	Vegetable, excluding tobacco	1901-23 003-007 1879-1900 003, 005-007
103	Vegetable, including tobacco	102 and 025
104 [†]	All agricultural, excluding tobacco	102 and 001
105	All agricultural, including tobacco	103 and 001
MANUFACTURED FOODS		
106 [†]	Meats	008-010 [*]
107 [†]	Animal, agricultural	106 and 011-012
108 [†]	Animal, all	107 and 013
109	Vegetable, agricultural, excluding beverages and tropical products	1899-1923 014-016, 018, 017 [*] 1879-98 014-015, 018, 017 [*]
110	Vegetable, agricultural	109, 019, and 021-023
111	Vegetable, all	110, 020 ^b , 024
112	Vegetable, including tobacco products	111 and 026
113 [†]	All agricultural	107 and 110
NONFOOD ANIMAL PRODUCTS		
114 [†]	Hides, leather, and products, crude, semimanu- factured and manufactured	027-029
115	All agricultural, crude and semimanufactured except fibers	027 and 032-033
116	All crude and semimanufactured, except fibers	1913-23 028, 030-031 ^c , 034, 115 1879-1912 028, 030, 034, 115
117	All, except textiles	116 and 029
NONFOOD VEGETABLE PRODUCTS		
118	All agricultural, crude and semimanufactured, except textiles	037 ^d -039
119	All crude and semimanufactured, except textiles	1899-1923 118 035, 040 1879-98 118 and 040
120 [†]	Cotton textiles, crude, semimanufactured and manufactured	1899-1923 042-044 1879-88 042 and 044
121 [†]	Manufactured textiles	1913-23 044 045, 048-049 1889-1912 044-045, 048, 049 [*] 1882-88 044-045 and 048 [*] -049 [*] 1879-81 044-045 and 048 [*]
122 [†]	Wood and manufactures, except paper	051-053
PRODUCTS OF ANIMAL OR VEGETABLE ORIGIN		
<i>Agricultural</i>		
123	Crude, excluding textiles and tobacco	027, 032, 037, and 039
124	Crude, excluding tobacco	1916-23 123, 042, 046, and 050 [*] 1899-1915 123, 042, and 050 [*] 1889-98 123, 042, 046, and 050 [*] 1879-88 123, 042, 046, and 050 [*]
125 [†]	Crude, including tobacco	124 and 025
126	Semimanufactures	033 and 038

(continued)

APPENDIX B
TABLE B-7 (concluded)

Export Class		Class Composition
PRODUCTS OF ANIMAL OR VEGETABLE ORIGIN (continued)		
<i>Nonagricultural</i>		
127	Crude	030 and 051 ^c
128†	Semimanufactures	1913-23: 028, 031 ^c , 034, 035, 040, 043, 047, 052, and 054 1899-1912: 028, 034, 035, 040, 043, 052, and 054 1898: 028, 034, 040, 052, 054 1879-97: 028, 034, 040, and 052
<i>Agricultural and Nonagricultural</i>		
129	Crude, excluding tobacco	124 and 127
130	Crude, including tobacco	125 and 127
131	Semimanufactures	126 and 128
<i>Crude and Semimanufactured Materials</i>		
132	Agricultural, excluding tobacco	124 and 126
133†	Agricultural, including tobacco	125-126
134	Nonagricultural	127-128
135	All, excluding tobacco	132, 134
136†	All, including tobacco	133-134
<i>Nonagricultural Products</i>		
137	Manufactures of animal or vegetable origin, excluding rubber	1899-1923: 029, 053, 121, 055 1879-98: 029, 053, 121, 055*
PRODUCTS OF OTHER THAN ANIMAL OR VEGETABLE ORIGIN		
138	Crude fuels	057-059
139†	Petroleum and products	1882-1923: 059, 060, 061 1879-81: 059, 061 1895-1923: 057, 058, 139 1879-94: 057, 139
140†	Fuels	066, 069
141†	Semimanufactured metals	1899-1923: 071, 072
142†	Machinery and automobiles and parts	1899-1923: 142, 070
143†	Manufactured iron and steel products including machinery and vehicles	1879-98: 070, 071
144†	Crude materials	1907-23: 138, 062, 065 ^f , 068 ^g , 073 1895-1906: 138, 065, 068, 073 1889-94: 135, 065, 078 1882-88: 138, 065, 068, 073* 1879-81: 138, 065, 073*
145†	Semimanufactures	1899-1923: 058, 060, 063, 141, 074 1895-98: 058, 060, 141, 063*, 074* 1882-94: 060, 141, 063*, 074* 1879-81: 141, 063*, 074*
146†	Manufactured metal products	1913-23: 143, 067 1879-1912: 143, 067*
147†	Manufactured products, including rubber, books, and other printed matter	1913-23: 036, 061, 064, 146, 075, 076*, 056*, 077* 1899-1912: 061, 064, 146, 075, 036*, 056*, 077* 1879-98: 061, 146, 075, 036*, 056*, 064*, 077*

NOTES TO TABLE B-7

† Annual Fisher price and quantity indexes and values are presented for these classes in Tables B-1 to B-6 inclusive

* Designates uncovered classes

▲ Class 002 is an uncovered class (see Appendix C), deflated here by price indexes for Class 013

▷ Class 020 is an uncovered class (see Appendix C), deflated here by price indexes for Class 019

◐ Class 031 is an uncovered class deflated here by price indexes for Class 030. Before 1913, Class 030 included commodities later listed in 031 (see Appendix C)

◑ Class 037 is an uncovered class for 1879-88 and 1913-23. During the 1889-1912 period, its price behavior was similar to that of Export Class 038. The indexes for class 038 were therefore used to deflate the values for 037 in 1879-88 and 1913-23

◒ Class 051 is uncovered because of difficulty in finding foreign prices for wood in log. It is deflated here by indexes for Class 052

◓ Class 065 is an uncovered class, deflated here by price indexes for Class 066

◔ Class 068 is an uncovered class for the period 1882-88 and 1895-98. Price indexes for Class 069 were used as deflators

APPENDIX B

TABLE B-8
LIST OF INTERMEDIATE IMPORT CLASSES

Import Class		Class Composition
CRUDE FOODS		
101	Animal	001-002 ^a
102†	Vegetable, except tropical	1912-23: 003-005, 007 1879-1911: 004-005, 007
103†	Vegetable, tropical	1889-1923: 006, 008-011 1879-88: 006, 008-010
104†	Vegetable, all	102-103
105	Vegetable, including tobacco	104, 024
106†	Agricultural, all	104, 001
107	Agricultural, including tobacco	105, 001
MANUFACTURED FOODS		
108†	Animal	012-013
109†	Vegetable, agricultural, excluding sugar and beverages	1899-1923: 014-018 1898: 014-016, 018, and 017* 1889-97: 014-016 and 017* 1882-88: 014, 016 1879-81: 014, 016, 017*
110†	Vegetable, agricultural	1919-23: 109, 019, and 021* 1913-18: 109, 019, 021 1889-1912: 109, 019, 021, 023 1879-88: 109, 019, 021
111†	Vegetable, all	1916-23: 110, 020 ^b , 022 1913-15: 110 and 022 1879-1912: 110, 020 ^b , 022
112	Vegetable, including tobacco products	111, 025
113†	Manufactured foodstuffs, agricultural	110, 012
NONFOOD ANIMAL PRODUCTS		
114†	Hides, leather and products	1891-1923: 026, 027 ^c , 028 1879-90: 026, 027 ^c , 028*
115†	Crude, agricultural, excluding fibers	1899-1923: 026, 031 1884-98: 026, 031*
116	Crude, all, except fibers	1879-83: 026 1882-1923: 115, 029, 032 1879-81: 115, 029
117	Crude and semimanufactured, except fibers	1899-1923: 116, 027, 030 ^d , 033, 034 1879-98: 116, 027, 030, 033, 034*
NONFOOD VEGETABLE PRODUCTS		
118†	Crude, agricultural, except fibers	036, 038, 040
119	Crude and semimanufactured, agricultural, except fibers	1915-23: 118, 039, 042 1879-1914: 118, 039
ANIMAL AND VEGETABLE FIBERS

APPENDIX B

TABLE B-8 (concluded)

Import Class	Class Composition
PRODUCTS OF MINERAL ORIGIN (continued)	
146† Semimanufactured metals	078, 081
147† Manufactured metal products	1899-1913, 1923: 079, 082, 084, 083* 1879-98: 082, 079*, 083*
148† Crude materials	1913-23: 143, 072, 074, 145, 085j 1899-1912: 067, 072, 074, 145, 085, 069* 1882-98: 067, 074, 145, 085 1879-81: 067, 145, 085
149† Semimanufactures	1906-23: 068, 070, 073h, 075, 146, 086 1889-1905: 070, 073h, 075, 146, 086 1884-88: 073h, 075, 146, 086, 070* 1879-83: 073h, 075, 146, 086
150† Manufactured products	1917-23, 1914: 087, 076, 071, 082, 084, 079*, 083*, 088* 1915-16: 087, 076, 082, 084, 079*, 083*, 088*, 071* 1913: 087, 076, 071, 147, 088* 1889-1912: 147, 076, 087, 088* 1879-88: 147, 076, 087*, 088*

NOTES TO TABLE B-8

† Annual Fisher price and quantity indexes and values are presented for these classes in Tables B-1 to B-6 inclusive. Data for import class 145 for 1879-88 are not included.

* Designates uncovered classes.

^a Class 002 is an uncovered class for the period 1879-88. We used the indexes for Class 013 as a deflator.

^b Class 020 is an uncovered class for 1879-88 and 1916-23. We used price indexes for Class 019 as deflators.

^c Class 027 is an uncovered class for the years 1889-1912. We used price indexes for Class 026 as deflators.

^d Class 030 is an uncovered class, deflated here by price indexes for Class 029.

^e Class 052 is an uncovered class for the period 1889-98. We used price indexes for Class 051 as deflators.

^f Class 058 is an uncovered class for the period 1882-98. In the 1899-1913 period, when all three indexes were available, those for Class 059, silk textiles, manufactured, resembled the ones for 058 much more than did the indexes for Class 057, silk textiles, crude. We therefore used the former as deflators.

^g Class 064 is an uncovered class for 1879-98. The price index for Class 063 followed that for 064 very closely from 1899 to 1923, and was therefore used as a deflator during the earlier years.

^h Class 144 extends back only to 1899 because there is no Class 072 before then. But the figures for Class 073, 1879-98, include semimanufactured precious stones and are therefore comparable with Class 144. Class 073 is an uncovered class, 1899-1912. We used the price indexes for Class 072 as deflators.

ⁱ Class 077 is an uncovered class for the period 1879-88. We used price indexes for Class 078 as deflators.

^j Class 085 is an uncovered class for the period 1879-98. We used as deflators the indexes for Class 086 whose movements were very similar to those of 085 during 1899-1912, although not during 1913-23.

Appendix C

Indexes and Values for Minor Classes, 1879-1923, and Description of Composition and Sources of Data

THIS appendix presents our new annual price and quantity indexes and values for selected minor groups, 1879-1923, together with descriptions of the composition and source notes for all minor groups

The minor groups vary a great deal in size, both as to value and number of commodities included. They are by no means all minor in importance, including, as they do, such items as imports of unmanufactured cotton (Import Class 045), exports of pork and related meat products (Export Class 009), and exports of grain (Export Class 005). They range from one-commodity classes such as exports of green coffee (Export Class 004) to imports of semimanufactured chemicals (Import Class 086) with commodity numbers for over 100 items.

Despite their differences in size and importance, these groups are the basic sampling units or blocks on which the various economic classifications were built (see Chapter 3). Some of the smaller classes were distinguished only to provide the flexibility necessary for various combinations: economic class, commodity group, or agricultural vs. nonagricultural. Others were distinguished for sampling reasons: their price behavior was distinctive and should not be applied to any uncovered commodities. For the most important groups, annual Fisher "ideal" price and quantity indexes and values are presented in Tables C-1 to C-6. Tables C-7 and C-8 list all minor classes and show the commodities included in each class, the years for which these commodities were covered or uncovered, the sources of price and quantity data, and other notes on the selection of commodities. Where no source notes are given, the data were obtained entirely from the official United States customs records (other sources are described in the notes). The customs records are published in the following sources:

Title	Dates	Agency
Monthly data		
Monthly Summary of Foreign Commerce of the U S	July 1914— Dec 1923	Bureau of Foreign and Domestic Commerce
Monthly Summary of Commerce and Finance of the U S	July 1912— June 1914	Bureau of Foreign and Domestic Commerce

APPENDIX C

Title	Dates	Agency
Monthly Summary of Commerce and Finance of the U.S.	July 1903— June 1912	Bureau of Statistics, Department of Commerce and Labor
Monthly Summary of Commerce and Finance of the U.S.	July 1898— June 1903	Bureau of Statistics, Treasury Department
Monthly Summary of Finance and Commerce of the U.S.	Jan. 1896— June 1898	Bureau of Statistics, Treasury Department
Finance, Commerce, and Immigration of the U.S.	Jan. 1895— Dec. 1895	Bureau of Statistics, Treasury Department
Summary Statement of the Imports and Exports of the U.S.	Jan. 1879— Dec. 1894	Bureau of Statistics, Treasury Department
Quarterly:		
Quarterly Report of the Chief of the Bureau of Statistics showing the imports and exports of the U.S.	1879— June 1893	Bureau of Statistics, Treasury Department
Annual:		
Foreign Commerce and Navigation of the U.S.	Fiscal years 1912-1918, Calendar years 1919-1923	Bureau of Foreign and Domestic Commerce
Foreign Commerce and Navigation of the U.S.	Fiscal years 1904-1911	Bureau of Statistics, Department of Commerce and Labor
Foreign Commerce and Navigation of the U.S.	Fiscal years 1893-1903	Bureau of Statistics, Treasury Department
Annual Report and Statement of the Chief of the Bureau of Statistics on the Foreign Commerce and Navigation, Immigration and Tonnage of the U.S.	Fiscal years 1885-1892	Bureau of Statistics, Treasury Department
Annual Report and Statement of the Chief of the Bureau of Statistics on the Commerce and Navigation of the U.S.	Fiscal years 1879-1884	Bureau of Statistics, Treasury Department

Additional official data compiled from the above sources were published in various issues of the *Statistical Abstract of the United States* and publications of *Imports and Duties*, giving data on imports for consumption for long periods. The latter were compiled under the direction of the House Ways and Means Committee by William W. Evans.

We also used a great variety of price data sources, both for comparison with unit values and as a substitute where unit values were not available. Some of the most frequently useful sources, with the abbreviations used in the notes to Tables C-7 and C-8 (which follow the tables), were :

Abbreviation in

U.K. export and import unit values	Statistical Office of the Customs and Excise Department, <i>Annual Statement of the Trade and Navigation of the United Kingdom</i> , London, and Great Britain Board of Trade, <i>Statistical Abstract of the United Kingdom</i> , London

One difficulty in the use of customs data is that of insuring the consistency of commodities over time. In the original source there are many changes of commodity title which do not involve changes in content, in other cases, titles remain the same while content changes. We have endeavored to correct for these inconsistencies by examining the unit values, watching for sudden changes in value, origin, or destination, and comparing general import figures with the more detailed imports for consumption data. For our covered commodities we expended considerable effort in this direction, but we were less energetic for uncovered commodities, where shifts did not appear to cross minor group lines. As long as the contents of a commodity title appeared consistent, or showed only insignificant shifts, we retained the same commodity number throughout, otherwise, a new number was given.

APPENDIX C

* Price and quantity indexes and values presented for these classes in Tables C-1 through C-6

APPENDIX C

NOTES TO TABLE C-7

Export Class

001

Items:

1. 1890-1923: BLS, Cattle, steers, good to choice.
1889: Aldrich, Beeves, live weight, Chicago.
1879-89: Aldrich, Beeves, good to prime, live weight, New York City.
2. 1890-1923: BLS, Hogs, good to choice, light butchers.
1889: Aldrich, Hogs, live weight, Chicago.
1879-89: Aldrich, Hogs, good to prime, live weight, New York City.
3. 1907-23: BLS, Lambs.
1890-1906: BLS, Sheep, native wethers.
1879-89: Aldrich, Sheep, good to prime, New York City.

003

Hay was separated from other vegetable foods because of differences in price behavior.

004

The series on green coffee begins with the inclusion of Puerto Rico in the U.S. customs area.

011

Before July 1882, commodities 5-7 were not listed separately in the published quarterly and monthly trade statements, but fiscal year annuals were available. We used these to estimate quarterly values by assuming that the ratio of these commodities to "all other articles" remained constant throughout each fiscal year. We obtained quarterly quantities from the published fiscal annual quantities by interpolating the unit values, using import unit values for lard as a guide.

013

Items:

1. Unit values were extrapolated back from fiscal 1887 by Bezanson price of salmon, Halifax.
5. Herring, salted or dry-cured was used as a covered item, 1915-23, when almost all of it consisted of shipments from New York to Latin America and the unit values moved similarly to BLS and WIB prices. Shipments in 1913-14 were mainly from the State of Washington to the Far East and at much lower unit values. We considered these to be non-comparable with later years and treated the item as uncovered.

014

Items 16 and 17 equal items 7-15.

018

Items:

6. BLS file, unpublished series, Peaches, cannery.
7. BLS file, unpublished series, Pineapples, cannery.

021

Items:

3. 1916-23: BLS price of pepper, black, Singapore, 1918 annual through 1923, extrapolated to 1918 quarterlies and 1916 by unweighted average of WIB prices for cassia, cloves, ginger, nutmeg, and black pepper, Singapore.
1884-88: Unweighted index of cloves and cassia from Bezanson, and nutmegs and Singapore pepper from Aldrich report.
4. Laspeyres price index of import unit values of coffee and cocoa with 1902 export weights.
5. Laspeyres price index combining price indexes used for items 3 (1884-88) and 4 (1884 weights).

APPENDIX C

NOTES TO TABLE C-7 (continued)

024

To a considerable extent, 1879-89 based on outside price data. Export unit values for alcoholic beverages became very erratic after 1918-19. The methods of obtaining them (shown below) are crude, but preferable to leaving a fairly large item incompletely covered or leaving the whole group uncovered from 1913 on.

Items

- 1 1919 export unit value extrapolated to 1920 by unit value of exports to all countries except Canada and China, to 1921 by unit value of exports to Canada, and to 1923 by the Canadian import unit value for imports of rum from the United States
- 2 First half of 1919 export unit values extrapolated to 1923 by U.K. annual export unit values of spirits
- 3 BLS price for bourbon, straight, four years in bond, in barrels, used for 1913 through first quarter of 1919. These were extrapolated to the rest of 1919 by U.S. export unit values and to 1920, 1921, and 1923 by U.K. export unit values of spirits
- 5 U.K. annual export unit values for spirits
- 13 Price per gallon of "whiskey, 32 u.p." in Toronto from *Statistical Contributions to Canadian Economic History*, Vol. II by K. W. Taylor and H. Michell, Toronto, 1931. The movements of this series followed closely those of the unit values of the main U.S. export item, bourbon, in the rest of this period.

026

To a considerable extent, 1879-98 based on outside price data.

Items

- 3 BLS, smoking tobacco
- 6 BLS, smoking tobacco
- 7 1889-97 Index of BLS, smoking tobacco, weighted 1 and BLS, tobacco, plug, smooth, weighted 3, 1890 to 1897. This was extrapolated back to 1889 by Aldrich, tobacco plug, navy, best grade
- 1884-88 Aldrich, tobacco plug, navy, best grade
- 8 Index of Aldrich, tobacco plug, navy, best grade and same, medium grade, and low grade, weighted equally

027

To a considerable extent, 1879-89 based on outside price data.

Item

- 8 1890-94, BLS, hides steers, green salted
- 1879-89, Aldrich, hides green salted

028

To a considerable extent, 1879-1910 based on outside price data.

Items

- 3 Prices for first and second quarters of 1920 were estimated from the unit value for the first half of 1920 and prices for 1919 were extrapolated from 1920, both by use of the average of patent chrome side upper leather and smooth black chrome side upper leather prices from Federal Trade Commission, *Report on Shoe and Leather Costs and Prices*, June 10, 1921. Prices for 1913-18 and earlier years from WIB, cattle, side-upper leather, patent chrome
- 12 Prices for 1911 and 1912 are unit values for commodity 1 of this class
- 22 1908-10 BLS, calf, chrome, range of first commercial grades, 1890-1907 calf, wax, 30-40 lbs to doz., 1884-89 Aldrich, leather calfskins, tanned and dressed, domestic, No. 1
- 26 Combination of Aldrich, upper leather and sole leather prices
- 27 Base price derived by extrapolating unit values by index used for item 26

029

Items

- 6 WIB prices for leather belting, 1913-18, extrapolated to 1919 quarterly, by

APPENDIX C

NOTES TO TABLE C-7 (continued)

BLS, men's shoes, vici calf. To obtain a base year price, the 1919 unit value is extrapolated to 1920 by the same BLS series, and from 1920-23, by export unit values for leather belting.

15. Interpolated between export unit values for 1896 and 1903 by an unweighted average of four BLS shoe prices.

030

Based to a considerable extent on outside price data. Quarterly indexes are largely interpolated.

Items:

1. Prices are a Laspeyres index (with 1923 weights derived from export values) of prices of skunk, muskrat, and opossum from *Fur News Magazine*, Columbus, Ohio. The source gave data for only the first and fourth quarters of each year, figures for the intervening quarters were interpolated.
2. 1907-12: Same index as for item 1.
1899-1907: To extrapolate the above index we used a Laspeyres index of Canadian prices of muskrat and skunk, still with 1923 U.S. export value weights. It seems likely that both of these indexes for 1899-1913 overweight skunk, whose price was increasing faster than that of the other furs.
1889-98: Unweighted index of prices of beaver, red fox, muskrat, raccoon, and skunk, from *Fur Trade Review*, New York, extrapolated by prices for the same furs from Bezanson.
1879-89: Unweighted index of Bezanson prices for beaver, red fox, gray fox, muskrat, raccoon, and skunk.

032

Based to a considerable extent on outside price data. Quarterly indexes were largely interpolated.

Items:

1. 1913-23: U.S. farm price of horses, U.S. Department of Agriculture, *Yearbook of Agriculture*, 1924, p. 985.
1899-1913: For 1899-1907, the price of draft horses at Omaha (USDA, *Yearbook*, 1907). The calculated calendar year 1907 average price was extrapolated to calendar year 1910 by the average farm price of horses two years and older, and for quarterly 1910-13, was extrapolated from calendar 1910 by average farm prices of all horses, from the 1924 USDA *Yearbook*. For 1908-09, first quarter prices were estimated by interpolating between first quarter 1907 and first quarter 1910 by the average value of all horses on farms, January, from the 1911 USDA *Yearbook*. The remaining quarters of 1908-09 were filled in by straight line interpolation.
1889-99: Omaha price of horses for 1897 to 1899. First quarter figures were extrapolated back to 1889 by average price of horses on farms in the U.S. and remaining quarters were interpolated on a straight line between Januaries.
5. 1915-21, 1923: Average prices of mules, St. Louis, USDA *Yearbook*, 1916, 1918, 1920, 1921, 1924.

033

Based to a considerable extent on outside price data.

Items:

5. Price of whale oil, crude no. 1: Av. price per pound, sellers' tanks, f.o.b. Pacific coast. Compiled from the *Oil, Paint, and Drug Reporter* and published in U.S. Dept. of Agriculture, Statistical Bulletin No. 59 (May 1937), *Fats, Oils, and Oleaginous Raw Materials—Production, Prices, Trade, Disappearance in the U.S., 1912-35 and Available Data for Earlier Years*. We used the Pacific Coast price because most of the whale oil was exported from West Coast ports.
14. Grease, white, average price per pound in tierces, New York. Same source as item 5.
16. Same as item 14.

APPENDIX C

NOTES TO TABLE C-7 (continued)

- 21 1899-1912 BLS price for tallow New York, extrapolated by Aldrich, tallow
1884-88 Aldrich price of tallow
- 034
Based to a considerable extent on outside price data
- Items
- 1 Prices are cod oil, Newfoundland tanked av price per pound in barrels, New York, compiled from the *Oil, Paint, and Drug Reporter* and published in U S Dept of Agriculture, Statistical Bulletin No 59, *Fats, Oils, and Oleaginous Raw Materials*
 - 2 Prices are Menhaden oil, light refined av price per pound, in barrels, New York, compiled from the *Oil, Paint, and Drug Reporter* and published in the same source as above
 - 3 Unit values extrapolated from 1920 to 1921 and 1923 by price of cod oil (see item 1)
- 035
To a considerable extent, 1899-1906 based on outside price data
- Item
- 2 1907 annual unit value extrapolated back to 1899 by BLS, rubber, Para Island, fine
- 036
The 1913-23 period is based on outside price data to a considerable extent
- Items
- 1 and 2 BLS, automobile tires, fabric
- 038
Item
- 8 1913-19 and 1923 Price index composed of coconut oil, weighted four times and soya bean oil weighted once. Weights were taken from earliest available values, those for the last half of 1919. Prices were from WIB and BLS
- 040
Item
- 5 Unweighted index of prices of chestnut extract, hemlock extract, and oak extract, from the *Oil, Paint, and Drug Reporter*
- 041
Item
- 6 Unweighted average of Bezanson prices of bergamot, cassia, and lemon oil, on 1889 base
- 043
Item
- 4 Unit values extrapolated from 1918 to 1913-17 by BLS, cotton, yarn, white, mule spun, northern, cones, 22/1
- 044
Items
- 14 Index composed of BLS underwear men's, cotton drawers and shifts, flat fleece, and BLS underwear women's cotton union suits, weighted equally with 1923 as base
 - 18 Index composed of underwear price index used for item 14, weighted once, and hosiery index weighted five times. The hosiery index is a combination of BLS, hosiery cotton, men's, BLS, hosiery cotton, women's mercerized, and BLS, hosiery cotton, women's, rib top
 - 57 BLS, Cotton yarns corded, white, mule-spun, northern, cones, 22/1
- 045
The 1884-1909 period is based on outside price data to a considerable extent
- Items
- 2-6, and 8 BLS, rope manila, 1st grade, $\frac{3}{4}$ " and large

APPENDIX C

NOTES TO TABLE C-7 (continued)

9. BLS, jute: raw, native firsts, actuals, extrapolated back from 1890 by Aldrich, jute, raw.
45. Export unit values for binder twine (item 1.) extrapolated back from 1910 to 1890 by BLS, rope, and to 1879-89 by export unit values of cordage (item 7.).

046

Based to a considerable extent on outside price data.

Items:

1. Data are not available for 1900-16. Quantities for 1916-23 are estimated from an index composed of BLS prices of wool: Ohio, fine, clothing, unwashed; and wool: Ohio, $\frac{1}{4}$ and $\frac{3}{4}$ grades, unwashed (med. grade), weighted equally, on a 1923 base. Quantities for 1889-99 are estimated from an index of the same two prices, on an 1899 base, extrapolated to 1889 by Aldrich price for wool: Ohio, fine fleece, scoured; and wool: Ohio, med. fleece, scoured. No quantities were estimated for 1879-88.

048

Based to a considerable extent on outside price data.

Items:

- 1-4. 1913-23: Quantities derived from a price index composed of BLS series for, overcoating: heavy; suiting: serge, 11 oz.; suiting: clay worsted, diagonal 16 oz.; uniform serge: wool-dyed, blue, 55-56", 16 oz.; suiting: serge, 9 $\frac{1}{2}$ oz., 55-57"; dress goods: women's broadcloth; dress goods: storm serge, all wool, double wrap. These were weighted equally, with 1923 as a base.
4. 1899-1913: Quantities derived from a price index composed of BLS series for overcoating: soft faced, black, 24 oz.; suiting: serge, 11 oz., 56-58"; suiting: clay worsted, diagonal, 16 oz.; uniform serge: all wool, indigo blue, 14 oz., 54"; suiting: serge, 9 $\frac{1}{2}$ oz., 55-57"; dress goods: women's, cashmere, cotton warp; dress goods: Panama cloth, 50". These were weighted equally, with 1913 as a base.
- 1892-99: Quantities derived from price index composed of BLS series for suiting: serge, 11 oz., 56-58", weighted twice; uniform serge: all wool, indigo blue, 14 oz., 54", weighted twice; dress goods: women's, cashmere, cotton warp, weighted once; and dress goods: Franklin sackings, 54", weighted once.
- 1890-91: Quantities derived from price index composed of BLS series for uniform serge: all wool, indigo blue, 14 oz., 54", weighted four times and the two series for dress goods used for the succeeding period, weighted once each.
- 1889: Quantities derived from Aldrich series for suiting: flannel, all wool, indigo blue, 6-4 Assabet, weighted six times; women's dress goods: all wool, ladies' cloth, 25", Assabet, opera, weighted once; and women's dress goods: all wool, ladies' cloth, 6-4, Assabet, weighted once.

049

Based to a considerable extent on outside price data.

Items:

1. BLS, hosiery: silk, women's, 39-42 gauge, full-fashioned, 7 thread.
11. 1913-17: Quantities estimated from index composed of WIB prices weighted by 1918 and 1922 export values. The price series used, and their weights, were as follows:

<i>Price Series</i>	<i>Weight</i>
Average of 3 series for ladies' hose	Fiscal 1918 export value, wearing apparel.
Average of 23 series for broad silk	Fiscal 1918 export value, broad silk dress goods.
Spun silk yarn, domestic, 60/1; and spun silk yarn, domestic, gray spun, 60/2, No. 1	Fiscal 1918 export value, other manuf. of silk multiplied by $\frac{1}{2}$ of the 1922 ratio of export values of thrown silk, spun silk, etc. to export values of other manufs. of silk.

APPENDIX C

NOTES TO TABLE C-7 (continued)

Price Series	Weight
Average of 2 velvet series, and average of 3 plush series	Fiscal 1918 export value, other manuf of silk, multiplied by $\frac{1}{2}$ of the 1922 ratio of export values of velvets, plushes, etc to other manuf of silk
Average of 2 ribbon series	Fiscal 1918 export value, other manuf of silk, multiplied by 1922 ratio of export values of ribbons exc velvet and plush to other manuf of silk
Average of 2 thread and embroidery silk series	Fiscal 1918 export value, other manuf of silk, multiplied by 1921 ratio of export values of sewing, embroidery, crochet silk to other manuf of silk

053

Based to a considerable extent on outside price data

Items

- 2 Price index for wooden chairs composed of BLS, bedroom chairs all gum, cane seat, weighted four times, BLS, bedroom chairs bedroom rockers, quartered oak, weighted twice, and BLS, dining room chairs set of six (composite), weighted fourteen times
- 3 Price index for other wood furniture composed of BLS, kitchen tables, weighted once, and BLS, bedroom sets, weighted six times
- 4 1913-17 Combination of index for item 2, weighted once and index for item 3, weighted twice
1899-1912 Price index composed of BLS, chairs bedroom, weighted twice, BLS, bedroom sets, weighted twelve times, BLS, kitchen chairs, weighted once, and BLS, kitchen tables, weighted twice
1889-98 Price index composed of BLS, bedroom chairs, maple, cane seat, N Y, weighted twice, BLS, kitchen chairs, weighted once, BLS, kitchen tables, weighted twice, and BLS, bedroom sets, weighted twelve times BLS series were extrapolated from 1890 to 1889 by corresponding Aldrich report series
1879-88 Price index composed of four Aldrich report series, weighted equally The series were bedroom set, painted, five pieces, chairs, bedroom, maple, cane seat, chairs, kitchen, common spindle, tables, kitchen, pine, 3 $\frac{1}{2}$ foot
- 5 1890-1923 BLS, doors, ponderosa pine
1884-89 Aldrich report, doors, pine, unmounted

055

The 1889-1910 period is based on outside price data to a considerable extent

Items

- 9 Price index composed of envelopes, manila writing paper, medium writing paper, good writing paper, and medium bond paper, weighted equally, on 1922 base *Data are originally from Paper Trade Journal, quoted in U'S Tariff Commission, Tariff Information Survey, Paragraphs 326 and 327 of 1913 (1922)*
- 10 Price index composed of BLS series for boxboard chip, no 90 to 50, boxboard chip, manila lined, single, boxboard liner, 85 lb test, and, for 1918 to 1923, boxboard manila lined, chip All are weighted equally, on a 1923 base
- 34 Price index composed of BLS, newsprint, weighted six times and three book paper prices weighted once each The book paper prices, which were compiled from the *Paper Trade Journal*, are for book paper, sized and super calendared, book paper, machine finish, and book paper, lithographing

059

Quarterly indexes are largely interpolated

The published export unit values for total crude petroleum could not be used for the last two periods, because they contain a strong downward bias which is due to the shift from high-quality, high priced Pennsylvania crude to the cheaper crudes of

APPENDIX C

NOTES TO TABLE C-7 (continued)

other regions. This phenomenon has been noted before in studies of mining output. For example, Harold Barger and Sam H. Schurr, in *The Mining Industries, 1899-1939: A Study of Output, Employment and Productivity* (NBER, New York, 1944, p. 191), separated Pennsylvania-grade oil from all other for the period 1899-1919 for this reason. Spencer and Wardwell in U.S. Bureau of the Census, *Raw Materials in the U.S. Economy: 1900-52*, Bureau of the Census Working Paper No. 1, Washington, D.C., 1954, p. 71, calculated that adjusting for the shift from Pennsylvania-grade crude between 1900 and 1925 would cut the growth of the index of petroleum output almost in half.

No data on the origin of crude petroleum exports are available to measure the shift, but its effects are observable: the unit value of crude petroleum exports fell by 25 per cent between 1902 and 1923, while the export unit value of illuminating oil, the BLS price of refined petroleum, for export, and the BLS price of Pennsylvania crude all rose by 40 per cent or more.

While there is no direct link between production and export data, we did find that the shift away from Pennsylvania-grade petroleum was reflected in a shift in customs area of shipment of crude petroleum exports. From East Coast districts, which were the natural outlets for Pennsylvania petroleum, and which had virtually a monopoly of crude exports in 1902, the trade shifted to Great Lakes, Pacific, and Gulf Coast districts. The hypothesis that this shift in port of export reflected a shift in origin was reinforced by the observation that unit values of crude exports from East Coast ports were considerably higher than the others. We attempted to correct for this bias by treating exports from each major area as a separate commodity, and then combining all of them in a Fisher "ideal" price index for the 1902-23 period. There were probably some shifts in the origin of crude petroleum exports before that, since the Lima-Indiana field became important in output as far back as the late 1880's. But we could not extend our procedure back any further because practically all exports went through East Coast ports before 1902. It is possible that Pennsylvania-grade crude maintained its dominance in exports longer than in domestic production for transportation reasons.

One possible indication of bias in the two earlier periods is the sharp fall, particularly between 1879 and 1893, in the margin between the export price of crude petroleum and the price (at the field) of Appalachian crude. This fall, however, may have been due to other factors, such as a decline in transportation cost; this is supported by the fact that there was a considerable fall also in the margin between the field price of Pennsylvania crude and the price at East Coast ports of refined oil for export.

Our index for 1902 to 1923 was an annual one, because the port data are not available quarterly. We converted the index to quarterly form by a freehand interpolation using the fluctuations of the original export unit values of crude and refined petroleum.

For 1879-98, unit values were used as published.

063

Item:

2. BLS price of gravel.

064

The 1899-1923 period is based on outside price data to a considerable extent.

Items:

1. Price index for 1918-23 composed of four BLS series weighted equally: fruit jars, quart, self-sealing; fruit jars, pint, self-sealing; fruit jars, quart, mason; and milk bottles, quart size. This index was extrapolated back to 1913 by WIB, glass milk bottles.
2. For 1899-1912, BLS price for glass, window, single B, 25" bracket. The same series was used for 1913-14 to extrapolate back the 1915 annual export unit value.

APPENDIX C

NOTES TO TABLE C-7 (continued)

- 4 1911-12 Average value per unit of fire bricks, from U.S. Interior Dept., *Mineral Resources of the U.S., 1912 and 1913*
- 5 1913-23 BLS price for roofing slate
1899-1913 Annual data for average value per unit of roofing slate from U.S. Interior Dept., *Mineral Resources of the U.S., 1913* We estimated quarterly prices by a freehand interpolation of these annual unit values.
- 6 1899-1912 BLS, brick red, common building, domestic.
- 7 BLS and WIB prices for hollow building tile
- 8 BLS, salt American medium.
- 9 BLS rubblers, table, price per dozen, f o b factory
- 27 Index composed of two WIB series dinnerware sets, best commercial grade, and dinnerware sets, decorated in cheap standard treatments weighted equally
The 1918 price was extrapolated to 1923 by BLS, plates white granite.

066

Items

- 2 Unit values of 3 and 6 used
- 10 BLS prices for brass sheets
- 19, 20, 25 BLS prices for aluminum 98-99 per cent.

067

The 1913-23 period is based on outside price data to a considerable extent.

Items

- 1 BLS price for brass sheets.
- 5 and 6 Unit values for Items 6-8, class 066 were used

068

The 1899-1912 period is based on outside price data to a considerable extent.

Import quantities and unit values are used for the period from 1913 to 1923, but for the years 1899 to 1912, we used the price of iron ore, mesabi, non Bessemer, from the *Iron Trade Review*

069

Items

- 3 1899-1903 BLS prices of tinplate, domestic, coke, at New York.
- 10 Price of steel bars, quarterly averages, from American Metal Market, *Metal Statistics, 1938*, New York, 1938

070

Based to a considerable extent on outside price data.

Items

- 2 1879-88 Prices of steel rails, at works in Pennsylvania, from U.S. Commissioner of Labor *Sixth Annual Report, 1890*
- 9 BLS price for saws crosscut, Champion, 6 ft, f o b factory
- 10 BLS price for hammers 1½ lbs, f o b New York
- 11 BLS price for shovels Ames, No 2
- 12 BLS price for locks common mortise
- 13 1913-23 BLS prices for structural steel structural shapes, beams, etc, 3" to 15", f o b mill
- 22 Unit values extrapolated back from 1906 to 1899 1905 by annual BLS series for cast iron pipe, lagged one year Quarterly prices were estimated by a free-hand interpolation
- 23 1913 23 BLS prices for knives and forks cocobolo handles
- 24 BLS price for augers regular, 1 inch
- 25 BLS price for files 8-inch mill, bastard
- 26 Price index composed of equally weighted BLS series for planes trowels, vices, and chisels, on 1923 base
- 27 Price index composed of equally weighted BLS series for planes, trowels, vices, chisels, augers, and files, on 1923 base

APPENDIX C

NOTES TO TABLE C-7 (continued)

28. Price index for 1918-23 composed of equally weighted BLS series for knobs: door; and butts, wrought iron, on a 1923 base. This is linked at 1918 to an index for 1913-17 on a 1918 base, composed of equally weighted WIB series for butts: wrought iron; hinges: spring hold back; lock sets; knobs: door; and hooks and eyes.
29. Price index composed of equally weighted BLS series for stoves: cooking, coal; stoves: cooking, gas, and stoves: cooking, oil.
30. For 1915-23, annual price index for "other track materials" from Engineering News-Record, *Construction Costs, 1935 edition*, p. 23. We extrapolated this index back to 1913 by an index made up of equally weighted prices for No. 9 Eureka spring frog, split switch, No. 9 rapid frog, and Positive rail anchors, from Presidents' Conference Committee, Western Group Office, *Material and Labor Index Numbers* (1927). Quarterly price indexes were estimated from these annual ones by a freehand interpolation.
90. Price index composed of equally weighted BLS series for planes, trowels, vises, chisels, shovels, augers, files, and hammers, on a 1913 base.
91. 1899-1912: Price index composed of equally weighted BLS series for knobs: door; locks: common mortise; and butts, on a 1913 base.
1889-98: Same as 1899-1912, but on an 1899 base, extrapolated from 1890 to 1889 by corresponding Aldrich series.
1884-88: Price index composed of equally weighted Aldrich series for door knobs, locks, and butts, on an 1889 base.
101. 1889-98: Price index composed of equally weighted BLS series (extrapolated from 1890 to 1889 by corresponding Aldrich series), for planes, trowels, vises, chisels, shovels, augers, files, hammers, and saws, on an 1899 base.
1879-88: Price index composed of equally weighted Aldrich series for same items as 1889-98, on an 1889 base.

071

Most of the coverage was achieved by the use of outside price data rather than by using the published quantity data from Commerce and Navigation reports. Since most of the price data were available only annually, we did not attempt to use available quarterly series. Instead, we computed only annual price indexes and converted them (by a freehand interpolation) to quarterly indexes. The latter were used only for combining with other groups.

Items:

1. 1913-23: Price index composed of the average of six BLS series for cultivators, weighted once, and the average of twenty BLS series for plows, weighted five times, with 1923 as a base.
1879-99: Our first step was the computation of a price index on a 1900 base for the years 1895, 1890, and 1880, from data in George K. Holmes, *Course of Prices of Farm Implements and Machinery for a Series of Years*, Department of Agriculture, Division of Statistics, Miscellaneous Series, Bulletin 18, 1901. This index was an equally weighted combination of a price index for plows, composed of 72 series for individual types, and a price index for cultivators, composed of 19 series. The second step was to interpolate this index between 1880 and 1900 and extrapolate to 1879 by an annual price series for plows given in T. S. Adams, *Prices Paid by Vermont Farmers for Goods and Services and Received by Them for Farm Products, 1790-1940; Wages of Vermont Farm Labor, 1700-1940*, Vermont Agricultural Experiment Station, Bulletin 507, February 1944.
2. Price index composed of price of planters (average of two BLS series), weighted once, and price of grain drills (average of four BLS series), weighted five times, on a 1923 base.
3. Average of six BLS series for rakes, weighted equally, on a 1923 base.
4. 1913-23: Average of three BLS series for mowers, weighted equally, on a 1923 base.

APPENDIX C

NOTES TO TABLE C-7 (continued)

- 1899-1913 For 1911-13 we used the index of prices paid by farmers for farm machinery except tractors, from Department of Agriculture, Bureau of Agricultural Economics, *Income Parity for Agriculture*, Part III, 1939. We extrapolated this back to 1903 by an index made up of equally weighted price relatives, on a 1911 base, for the following items: Deere grain binder, 6 ft., 7 ft., and 8 ft.; International Harvester grain binder, 5, 6, 7, and 8 ft.; Deere corn binder, International Harvester corn binder, Deere mower, 5 ft. regular, 5 ft. vertical, and 6 ft.; and International Harvester mower. These data were from U.S. Bureau of Corporations, *The International Harvester Company*, 1913. We then extrapolated the index back to 1899 by an equally weighted average of series for mowing machines and plows from Adams, *Prices Paid by Vermont Farmers*.
- 1879-99 Indexes covering 1895, 1890, and 1880 on a 1900 base for mowers (composed of twelve series, equally weighted) and for reapers (composed of seven series, equally weighted) were constructed from data in Holmes, *Prices of Farm Implements* and were combined, again with equal weights. We then interpolated between 1880 and 1900 and extrapolated to 1879 by the price series for mowing machines from Adams, *Prices Paid by Vermont Farmers*.
- 5 Average of three BLS price series for cream separators
 - 6 Average of two BLS price series for threshers
 - 7 Price index composed of (1) An average, weighted three times, of thirteen BLS series for harrows and manure spreaders, (2) an average, weighted three times, of one BLS series for grain binders, three series for corn binders, one series for hay loaders (itself an average of three), one series for potato diggers (itself an average of two), three series for ensilage cutters, and one series for a cornpicker husker, (3) an average, weighted once, of four BLS series for milking machines, (4) an average, weighted three times, of two BLS series for spraying outfits and four series for wagons
 - 8 An equally weighted average of seven BLS tractor series
 - 9 An index composed of all the series used for item 7, with the same weights, combined with the index used for 8, weighted twice
 - 13 Price index for turbogenerators from William W. Handy, *The Yardstick of Public Utility Operations and Construction Costs*, Baltimore, 1929
 - 14 Price index for motors from *ibid*
 - 15 Price index for pumps from *ibid*
 - 16 ICC index of price of passenger train cars, 1915-23, published in *Railway Age*, July 25, 1936, Vol. 101, No. 4, extrapolated back to 1913 by corresponding index from Presidents' Conference Committee, Eastern Group Pamphlet 138-6, *Trend of Prices for Locomotives, Freight and Passenger Train Cars and Floating Equipment*, August 15, 1930
 - 17 ICC index for freight train cars extrapolated by PCC index (see item 16)
 - 18 BLS price for wagons, 2 horse, with bed, no brake-composite
 - 19 Value per unit of bicycles produced in the U.S., 1914, 1919, 1921, and 1923 interpolated by export unit values for motorcycles. Bicycle prices are Census of Manufactures data reproduced in Solomon Fabricant, *The Output of Manufacturing Industries, 1899-1937*, NBER, New York, 1940, p. 590
 - 22 1913-23 BLS price for sewing machines, foot treadle
1879-1913 Canadian import unit values for sewing machines from the U.S., centered to approximate calendar year figures. Data are from various issues of the *Canada Yearbook*, the *Report of the National Revenue Department of Canada*, and the *Sessional Papers of the Canadian Parliament*
 - 23 1913-23 ICC index for steam engines extrapolated to 1913 by PCC indexes (see note to item 16)
1899-1913 Export unit values, 1899 to 1910, extrapolated to 1913 by PCC index.
 - 24 ICC index for locomotives other than steam, 1915 to 1923, extrapolated to 1913 by PCC index for steam locomotives

APPENDIX C

NOTES TO TABLE C-7 (continued)

25. Machine tool price index from Presidents' Conference Committee, Western Group Office, *Materials and Labor Indexes*, p. 61.
 26. ICC index of railroad shop machinery costs.
 27. For 1900 to 1917 and 1923, price index for shop machinery and machine tools, equally weighted. The index for shop machinery is the ICC index extrapolated back from 1915 by the Presidents' Conference Committee series, published in Presidents' Conference Committee, Eastern Group Pamphlet 314, *Trend of Cost of Shop Machinery*, Jan. 1926. The machine tool price index is from the source listed for 26. For 1898 and 1899, this index was extrapolated back by the shop machinery price index alone.
 28. Index of the cost of woodworking machinery, from same source as item 25.
 29. Price index for "substation apparatus" from Federal Communications Commission, *Telephone Investigation, Special Investigation Docket #1, Exhibit #2091, Western Electric Co. Profits and Price Trends*, June 14, 1937, p. 270.
 - 30 and 31. Price index composed of the following BLS series for engines, on a 1923 base: 3 hp single cylinder, horizontal hopper cooled, weighted once; less than 5 hp hopper cooled, weighted once; 5-10 hp inclusive, weighted twice; more than 10 hp weighted six times.
 32. Index composed of four equally weighted price series for insulated wire and cable from Handy, *Tardstick*.
 33. Price index for power transformers from *ibid*.
 34. Price index for boilers from *ibid*.
 67. Canadian import unit values for typewriters from the U.S., centered to approximate calendar years. For sources, see item 22.
 105. For 1911-12, index of prices paid by farmers for farm machinery other than tractors, from Department of Agriculture, Bureau of Agricultural Economics, *Income Parity for Agriculture*, Part III, 1939. We extrapolated this series back to 1903 by an unweighted average of prices for rakes, tedders, disk harrows, and manure spreaders, from U.S. Bureau of Corporations, *The International Harvester Company*, 1913, and from 1903 back to 1899 using an unweighted average of the Adams series for mowing machines and plows (see notes to item 1).
 106. PCC index of the cost of woodworking machinery. For source, see item 25.
 107. A combination of PCC indexes for freight cars, weighted five times, and passenger cars, weighted once. For source, see item 16.
 125. Canadian import unit values for bicycles from the U.S. centered to approximate calendar year figures. For source, see item 22.
 129. Price index for 1895, 1890, and 1880 on a 1900 base, composed of equally weighted series for harvesters, tedders, and rakes, from Holmes, *Prices of Farm Implements*. This index was interpolated between 1880 and 1900 and extrapolated to 1879 by a price index for farm machinery other than motor vehicles from Adams, *Prices Paid by Vermont Farmers* which is itself extrapolated from 1831 back to 1879 by the Adams series for plows.
- 072
- Based to a considerable extent on outside price data. Quarterly indexes are largely interpolated.
- Items:
1. 1913-23: BLS index for passenger automobiles.
 1. 1899-1906 and 2, 1907-12: The annual index for the periods was constructed in several segments as follows:
 - 1910-13: Index composed of prices of Ford 4.22 hp, weighted four times; Buick-7 passenger, weighted twice; Buick-5 passenger, weighted twice; and Overland 4.18 hp, weighted once. Prices are from U.S. Tariff Commission, *Tariff Information Surveys, Automobiles, Bicycles, Motor Cycles, and Axles*, GPO, 1921.
 - 1909: Index for 1910 extrapolated back to 1909 by price of Ford Model T touring car (same one used for 1910-13) from Federal Trade Commission, *Report on the Motor Vehicle Industry*, p. 632, quoting U.S. Board of Tax Appeals Reports, Vol. 11, p. 1116.

APPENDIX C

NOTES TO TABLE C-7 (continued)

- 1904-08 We constructed a Fisher "ideal" index for 1904 on a 1909 base for open passenger cars 2-door, and open passenger cars 4-door, using Census of Manufactures data on unit values of cars produced in the U.S. as quoted in Solomon Fabricant, *The Output of Manufacturing Industries, 1899-1937*, NBER, New York, 1940. We then interpolated this index between 1904 and 1909 by an equally weighted combination of our indexes for mowers and reapers (item 4, class 071) and other agricultural machinery (item 102, class 071).
- 1900-03 The index for 1904 was extrapolated back to 1900 using the unit value of passenger cars produced in the U.S. from Automobile Manufacturers Association, *Automobile Facts and Figures*, 1952.
- 1899 The 1904 index was extrapolated back by the unit value of complete vehicles and chassis, produced in the U.S. These are Census of Manufactures data quoted in Fabricant, *Output of Manufacturing Industries*, p. 578.
- Quarterly indexes used only for combining with other groups, were estimated by a freehand interpolation. Values for 1899 to June 1901 were included with "cars, carriages, and other vehicles and parts of" in the published figures. We made very crude estimates of these values to complete the period.

073

Items

- 5 and 6 Export unit values for crude fertilizers moved very differently from domestic prices between 1889 and 1913, they changed only slightly during the whole period, particularly after 1899 while domestic prices fell by over 50 per cent between 1890 and 1897 and then rose by 50 per cent or more by 1907-08. By contrast the total range of the export unit values between 1893 and 1912, was from \$7.41 to \$8.42 per ton. Exports through individual customs districts were still steadier in price. Exports through the Fernandina, Florida district, for example, were reported at exactly \$10.00 per ton for every year checked between 1899 and 1912. The same was true of Brunswick, Georgia, and, with a few exceptions, of Jacksonville, Florida and Savannah, Georgia. Another important customs district Tampa, Florida, reported exactly \$6.00 per ton for many years. The contrast between the movements of export and domestic prices and the peculiar stability of the customs district unit values would have led us to discard the export unit values if there had been no information to confirm them. But we found that United Kingdom import unit values of crude fertilizers exhibited very similar stability during this period and therefore accepted the U.S. figures.

074

Based to a considerable extent on outside price data.

Items

- 5 Values for 1923 estimated from values of white and sublimed lead, using 1922 ratio. Prices estimated by extrapolation from 1922 using BLS series for lead, carbonate of (white lead) American, in oil.
- 13 1899-1912 Price series for ammonia sulphate from E. E. Vial, *Prices of Fertilizer Materials and Factors Affecting the Fertilizer Tonnage*, New York State, Cornell University Agricultural Experiment Station, Mimeo 119.
- 14 BLS price series for benzol.
- 15 BLS, nitric acid.
- 16 BLS, acetic acid.
- 17 BLS, boric acid.
- 18 Index, on a 1923 base, of BLS prices for muriatic acid, weighted once, stearic acid, weighted once, oleic acid, weighted once, acetic acid, weighted once, and boric acid, weighted twice.
- 19 Index, on a 1923 base, of equally weighted BLS prices for muriatic acid, stearic acid, and oleic acid.
- 20 BLS picric acid.
- 21 1913-17 Index composed of BLS, picric acid, weighted five times, BLS, carbolic acid, weighted once, and the index for item 19, weighted once.

APPENDIX C

NOTES TO TABLE C-7 (continued)

- 1909-12: Index composed of equally weighted series for muriatic acid, from BLS, and nitric and stearic acid, from the *Oil, Paint, and Drug Reporter*.
22. 1918-23: Index composed of equally weighted BLS series for jet nigrosine, water soluble #845; direct black, #582; sulphur brown, #1177; and indigo, 20% paste, #1177; on a 1923 base.
- 1913-17: The above index was extrapolated back to 1913 by one composed of the same series plus WIB series for chrysoidine Y and chrysoidine R, all on a 1918 base.
23. BLS price of logwood extract, solid.
24. Index composed of equally weighted *Oil, Paint, and Drug Reporter* series for fustic extract, solid, and quercitron extract, 51°.
25. 1913-17: Index composed of equally weighted series in items 23 and 24.
- 1899-1912: Index composed of equally weighted *Oil, Paint, and Drug Reporter* series for logwood extract, solid, and synthetic indigo, on a 1913 base.
27. The price index is composed of equally weighted indexes for mineral earth pigments and chemical pigments which were constructed as follows: The mineral earth pigment index was composed, for 1918 annual and 1919-23, of BLS series for barytes and whiting, equally weighted; and for 1913-17 and 1918 quarterly, of the same two plus WIB series for ocher, umber, venetian red, and paris green, also weighted equally. The chemical pigment index was composed, for 1918 annual and 1919-23, of equally weighted BLS series for lithopone and cadmium sulphide; for 1918 quarterly, of the same two plus WIB series for chrome yellow, chrome green, prussian blue, and ultramarine; and for 1913-17, of the same series with the exception of cadmium sulphide, all equally weighted.
28. 1913-23: BLS price for lampblack.
- 1899-1912: Index composed of equally weighted prices of carbon black, lamp-black, and bone black, from the *Oil, Paint, and Drug Reporter*.
30. Price of collodion, flexible, New York spot, from the *Oil, Paint, and Drug Reporter*, Sept. 1915 through 1923. The 1918 fiscal annual was extrapolated to fiscal years 1913-15, and interpolated freehand for quarterly estimates.
- 37, 38 and 39. Index composed of equally weighted BLS series for soda ash and caustic soda.
40. BLS, tar.
41. BLS, benzol.
43. BLS, formaldehyde.
54. BLS, sulphuric acid, 66°.
55. Index composed of equally weighted BLS series for sulphuric acid and muriatic acid, and *Oil, Paint, and Drug Reporter* series for nitric acid and stearic acid, on a 1913 base.

075

To a considerable extent, 1879-99 based on outside price data.

Items:

10. Index composed of equally weighted BLS series for white lead, putty, and zinc oxide, on a 1923 base.
11. Index composed of the index for item 10, weighted five times, and an index made up of equally weighted WIB prices for red lead and litharge, weighted once.
12. WIB toilet soap, 1913-18, extrapolated to 1923 by export unit value for item 8.
30. Index, on a 1913 base, composed of equally weighted BLS series for lead: white, in oil, basic carbonate; and zinc oxide: leaded grades, 5% pigment.
33. 1889-99: Same as item 30; 1890-99, extrapolated to 1889 by corresponding Aldrich series.
- 1879-89: Index, on an 1889 base, composed of equally weighted Aldrich series for zinc oxide and Bezanson series for lead: white, dry; lead: white, in oil; and lead: red, dry.

076

Includes items not classified elsewhere. Values range from \$2.5 million to \$16.3 million.

TABLE C-8
COMPOSITION AND COVERAGE OF MINOR IMPORT CLASSES

Import Class and Commodity Composition	Years		Import Class and Commodity Composition	Years	
	Covered	Uncovered		Covered	Uncovered
001 Crude animal foods, agricultural			002 Crude animal foods, nonagricultural (CONT)		
1 Cattle	1884-1923		7 Salmon, fresh	1889-1908	1884-88, 1919-23
2 Items 8, 9	1913-23				
3 Poultry eggs in shell	1879-98, 1914-23		8 Other shellfish crabs, shrimps, lobsters		1913-23
4 Swine		1916-21	9 Items 3, 7	1913-18	
5 Other live food animals, free		1916-21	10 Items 4, 7	1913-18	
6 Items 4, 5		1884-1915, 1922-23	11 Items 5, 7	1913-18	
			12 Items 6, 7	1913-18	
7 Other live food animals, dutiable		1884-1923	13 Items 3-7	1909-12	1879-83
8 Sheep, free	1884-1912		14 Fresh fish exc salmon	1889-1908	1884-88
9 Sheep, dutiable	1884-1912		15 Items 1, 2, and 8		1903-12
10 All live animals, free					
11 All live animals, dutiable		1882-83	003 Hay	1912-23	
		1879-81	1 Hay		
			004 Grains		
			1 Wheat	1879-1923	
002 Crude animal foods, nonagricultural			2 Oats	1879-88, 1899-1923	1889-98
1 Lobsters, other than canned	1913-23		3 Corn	1913-23	1879-98
2 Crabmeat	1913-23		4 Rice uncleaned	1913-21	1922-23
3 Halibut	1919-23		5 Barley	1879-98	
4 Whitefish	1919-23		6 Rye		1879-98
5 Mackerel	1919-23				
6 Herring	1919-23		005 Vegetables, crude		
			1. Onions	1897-1923	
			2 Beans, dried	1910-23	

005 <i>Vegetables, crude (CONTR.)</i>	3. Peas, dried	1912-23

^a Price and quantity indexes and values presented for these classes in Tables C-1 through C-6.

APPENDIX C

NOTES TO TABLE C-8

Import Class

001

Based to a considerable extent on outside price data

Items

- 1 1890-1923 Canadian price of butcher's cattle choice steers, price per cwt at Toronto, from various issues of Canada, Dominion Bureau of Statistics, Internal Trade Branch, *Prices and Price Indexes*, and Canada, Dept of Labour, *Wholesale Prices in Canada*
- 1884-89 Canadian price of cattle, live—1st quality (export steers), price per cwt in Toronto, from K W Taylor and H Michell, *Statistical Contributions to Canadian Economic History*, Vol II, Toronto, 1931
- 2, 8, and 9 Canadian price of sheep, price per cwt at Toronto For sources see item 1
- 3 1889-99 Canadian wholesale price of eggs storage, in case lots, at Toronto, 1890-99, and of eggs (new laid), 1889 For sources see item 1

002

To a considerable extent, 1889-1923 based on outside price data Quarterly values for items 9-12 for 1913-18 were estimated from quarterly data for imports of total fresh fish including salmon and annual data on Canadian exports, by type of fish In order to simplify index computations, imports for item 7 were not estimated separately (we had no price index to use for fresh salmon) but were distributed proportionately among the other types

Canadian price data are from *Prices and Price Indexes* and *Wholesale Prices in Canada*

Items

- 3 and 9 Canadian price of halibut, fresh, white, at Canso, N S
- 4 and 10 Canadian price of whitefish, at Toronto
- 5 Canadian price of mackerel, salted, at Halifax.
- 6 Canadian price of herring, salted, at Halifax.
- 11 Same as item 5, for 1913 Extrapolated to 1918 by mackerel, at Montreal
- 12 Same as item 6, for 1913 Extrapolated to 1918 by herring, salted, at Canso, N S
- 13 and 14 Canadian price of whitefish, at Toronto

004

To a considerable extent, 1889-1913 based on outside price data

Items

- 1 1913-23 Imports of wheat, mainly from Canada, were responsible for the growth of this class Approximately half of the \$45 million of wheat grain imported in 1922-23 were for milling in bond and export as flour The rest, imported for U S consumption despite the \$30 a bushel tariff (roughly 30 per cent) imposed in 1921, was apparently hard red spring wheat, superior to most U S wheat (see Henry C. Wallace, *The Wheat Situation A Report to the President*, Washington D C, 1922, pp 13, 27, 31-32)
- 1889-1913 Canadian wholesale prices of wheat, Ontario, No 2, White
- 2 1889-1913 Canadian wholesale price of oats, Western, No 2, White
- 3 Instead of following domestic prices, the import unit values for corn used here follow those from Argentina, these in turn resemble the spot price of corn in Buenos Aires (U S Department of Agriculture, *Yearbook*, 1924, p 615)
- 4 Rice has been treated as a covered item from 1913 through 1921, but we have used as a base the 1923 import unit value from Japan only It was not clear that the fall in price from 1921 to 1923 occasioned by the shift from Japanese to Mexican rice, was a price, rather than quality, change As we have used it, the unit values follow fairly closely the Tokyo price of average quality brown rice (see V D Wickizer and M K Bennett, *The Rice Economy of Monsoon Asia*, Food Research Institute, Stanford University, California, 1941)

APPENDIX C

NOTES TO TABLE C-8 (continued)

5. For a few quarters in 1896 and 1898, when quantities imported were small and unit values showed violent fluctuations unrelated to price movements, we discarded the unit values and interpolated by the Canadian wholesale price of barley, Ontario No. 2.

005

Items:

4. Potatoes were imported mainly from Canada during 1917-18; we therefore used these imports alone for the 1923 base.
6. 1919-20: The 1923 import unit value of potatoes from Canada was used to estimate base-year quantity because Canada was the main source of imports in 1919 and 1920.

1899-1913: In this period, fluctuations in import unit values for potatoes were violent and largely inverse to those of the American domestic price. Imports of potatoes were of two distinct types: those from the United Kingdom, which came in large amounts, but sporadically, mainly in years when the American domestic price was high, and more stable import quantities from Bermuda, with unit values about three times as high as those from the U.K. Thus, when U.S. prices were high, imports were dominated by low-priced potatoes from the U.K., and the unit value was therefore low, but when U.S. prices were low, imports were dominated by the high-priced imports from Bermuda, and the unit values were therefore high. Since we were more interested in coverage for the years when imports were large, we tried to put together a series that would be consistent for those years and would follow the movements of U.K. export unit values which are shown in U.K. Statistical Abstracts. We did not use the unit values for each quarter of every year, but only those, mainly the large ones, which followed the pattern of the U.K. export prices. We then applied these quarterly unit values to the rest of their respective years, in place of the actual ones. For this reason, the quarterly movements of the series are somewhat arbitrary.

1879-99: The procedure used here was similar to that for the 1899-1913 period, but the annual fluctuations followed U.K. prices much better and fewer of the quarterly changes had to be smoothed out.

006

The 1879-83 period based on outside price data.

Item:

17. Prices are a weighted index (with fiscal 1883 imports-for-consumption weights) of Bezanson series for pepper, pimiento, cassia, cloves, and nutmeg, with fiscal 1883 as 100. To arrive at a base year price, the index is extrapolated to 1889 by a Fisher "ideal" index of the import unit values of pepper and nutmeg.

007

To a considerable extent, 1879-99 based on outside price data.

Items:

10. Import unit values extrapolated back from 1919 to 1907 by import unit values of copra, not prepared.
13. 1889-99: The 1899 U.S. import unit value is extrapolated back to 1895 by United Kingdom import unit values, and from 1895 back to 1889 by Bezanson prices of lemons from Sicily. Italy was the main source of lemon imports.
- 1884-89: Bezanson prices of lemons.
18. 1889-99: The U.S. annual 1900 import unit value was extrapolated back to 1893 annually by U.K. import unit values. Approximate quarterly values were obtained by using British values, roughly deseasonalized and then multiplied by a crude American seasonal index derived from import unit values for 1899-1905. The resulting quarterly series was then adjusted to the level of the

APPENDIX C

NOTES TO TABLE C-8 (continued)

- annual series The 1893 annual unit value was then extrapolated back to 1890 by a similar process using U K values for lemons and oranges combined, and to 1889 by U S imports-for-consumption unit values for oranges in boxes, 1 5 to 2 5 cubic feet
- 1884-88 U S imports-for consumption unit values averaged to estimate calendar year prices and multiplied by the seasonal index mentioned above to get quarterly prices
- 24 1879-89 Import unit values extrapolated back to 1879 from 1884 by Bezanson prices of almonds
- 25 The trend in general import unit values of walnuts was biased upwards because of a shift from unshelled to shelled nuts We were able to construct a fiscal annual Fisher "ideal" index from imports-for consumption data for the two types separately, and we adjusted the quarterly general import unit values to the movements of this index
- 36 Import unit values extrapolated from 1884 back to 1879 by Aldrich prices of prunes, Turkish
- 38 Aldrich prices of currants, Zante
- 41 Import unit values extrapolated back from 1884 to 1879 by Bezanson price of raisins, Valentinia
- 42 Annual export unit values of bananas from Jamaica, D W Rodriguez, *Bananas An Outline of the Economic History of Production and Trade With Special Reference to Jamaica*, Department of Agriculture, Commodity Bulletin No 1, Kingston, Jamaica, 1955 These were multiplied by a seasonal index derived from 1908-11 U S import unit values Quarterly values for 1879-83 were estimated by annual imports for-consumption ratios from general imports data for all other fruits
- 46 Price index for lemons and oranges, with 1884 weights consisting of the Bezanson price of lemons and an orange price series constructed from Jamaican annual export unit values multiplied by the seasonal price index described above (Item 18) The Jamaica export unit values are from Great Britain, Parliament, *Sessional Papers*, 1892 Quarterly import values for oranges and lemons were estimated from quarterly import values for all fruits by the use of annual ratios from imports-for-consumption data

008

Tea imports were broken down by country in 1913-23 to eliminate the effects of shifts among qualities and types of tea There was a wartime shift, partially reversed afterwards, in the origin of black tea, from Great Britain to the British and Dutch East Indies, and there was a long term trend, in evidence since the 1890's, away from green tea (mostly from China) to black tea (from India and Great Britain) We were not able to make the same breakdown of quarterly import data in the 1899-1913 period, and the price index for those years is therefore biased upwards, since black tea was more expensive than green tea

011

To a considerable extent, 1899-1907 based on outside price data

1913-23 Import unit values for bananas are dubious on two counts First, they did not follow closely the price of bananas in New York during 1913-23, the only period for which we could make a comparison Second, they involve, to some extent, transactions by American companies with their own subsidiaries in a product for which the market is not developed in the producing country For these reasons there is considerable doubt as to the meaning of any price that might have been reported We decided to use the unit values, however, because the figures for different countries of origin show similar movements and because they agree quite well with export unit values reported by the countries of origin, where we could make the comparison

APPENDIX C

NOTES TO TABLE C-8 (continued)

1899-1913: Quarterly import unit values were used for 1908-13. The U.S. import value was then extrapolated back from 1908 to 1900 by United Kingdom import unit values multiplied by the seasonal pattern for U.S. import values, 1908-11. The series was then extended back to 1899 by the export unit value of bananas from Jamaica, also multiplied by the U.S. seasonal pattern.

1889-99: Jamaica export unit values multiplied by U.S. seasonal price pattern, 1908-13. Jamaica export unit values are from D. W. Rodriquez, *Bananas: An Outline of the Economic History of Production and Trade with Special Reference to Jamaica*.

012

To a considerable extent, 1879-83 based on outside price data.

Items:

1. Unit value extrapolated back from fiscal 1884 by Canadian wholesale price of butter (dairy prints) in Toronto. Values estimated from values for provisions using annual ratios from imports-for-consumption data.
2. Canadian wholesale price of milk: prices paid to producers, Montreal.
10. Unit values extrapolated back from fiscal 1884 by Canadian wholesale price of cheese (new large) in Toronto. Values estimated as for item 1.
- 11 and 12. 1913 figures are derived from imports-for-consumption data.
- 13 and 14. General import data give only the combination of mutton and lamb. We separated them using annual ratios derived from imports-for-consumption data.

013

Item:

5. Unit values extrapolated back to 1913 by using the last half of 1918 ratio, by the WIB price for sardines, $\frac{1}{4}$ oils, keyless, canned.

017

To a considerable extent, 1899-1918 based on outside price data.

Item:

2. 1913-23: Import unit values extrapolated back from 1919 to 1914-18 by export unit values for pearl tapioca from the Straits Settlements. These data are from Straits Settlements, Import, Export, and Statistical Office, *Return of Imports and Exports*. These prices were extrapolated to 1913 by Canadian wholesale prices of tapioca, medium pearl, at Toronto.
- 1899-1913: Canadian wholesale prices of tapioca.

020

Item:

3. Import unit values extrapolated back from 1891 to 1889 by import unit values for class 019, item 6. The very sharp rise in imports of refined sugar after 1890 is due to the cut in tariffs under the 1890 Act. The rate dropped from 3-3.5 cents per pound (roughly 60 to 90% ad valorem), to .5-.6 cents (about 12 to 17% ad valorem).

021

1923 import unit values for malt liquors estimated from U.K. export unit values and for still wines, from U.K. import unit values.

022

Items:

2. Import unit value for 1923 estimated by using Canadian import unit value for countries other than the U.S. and the U.K.
- 3 and 4. Import unit values for 1923 estimated by using U.K. export unit values.

APPENDIX C

NOTES TO TABLE C-8 (continued)

023

Items

- 1 Quarterly import quantities were adjusted to the level determined by a fiscal year Laspeyres index, on a calendar 1913 base, of imports for consumption unit values for capsicum, or red pepper, mustard seed, ground, and sage
- 2 Quarterly import quantities were adjusted to the level determined by fiscal year imports for consumption unit values for mustard seed, ground or prepared, which was, by far, the main component of the group

024

Item

- 12 1889-90 General import data combined leaf suitable for cigar wrapping with all other leaf before 1891 Since the former was almost twice as expensive as the latter, we adjusted the published quarterly quantities to the level implied by a fiscal year index of the two types separately, computed from imports-for consumption data The earlier figures were not adjusted because tobacco for cigar wrapping was of minor importance before 1889 We did, however, set the 1889 base year price at the 1888 level to eliminate the effect of the shift to tobacco for cigar wrapping

025

Cigars, cheroots and cigarettes from the Philippine Islands were much lower in price than those from other countries and were admitted free of duty Before they became free, in 1909, imports from this source were negligible We therefore used as a base the unit value for imports from countries other than the Philippine Islands

026

Items

- 4 Adjusted for shifts among countries of origin 1913-June 1917 A fiscal Fisher index using general imports country data was computed on a calendar 1923 base for "calfskins, dry and dry salted" from two groups of countries Group 1 Finland, France, Germany, Latvia, Norway, Russia, and Dutch East Indies Group 2 England, Canada, Argentina, Uruguay, New Zealand, British India, and Denmark Quarterly quantities were adjusted to level of new fiscal quantities
- 10 and 11 1923 annual value estimated from "total sheep and lamb skins" by the ratio for the nine months ending September 1922 1923 annual quantity figure obtained by using a price extrapolated from that of the nine months ending September 1922 by "total sheep and lamb skins"

027

To a large extent, 1883-89 and 1916-23 based on outside price data

Items

- 1 1919 unit value extrapolated back to 1918 by Canadian wholesale price of sole leather, green hide crops
- 2 Prices extrapolated back from 1919 and forward from 1921 by BLS, leather glazed kid, black, top grade from Brazilian skins, No 3030
- 3 1919-23 prices are Canadian wholesale prices of box sides "B", extrapolated back to 1916-18 by Canadian wholesale prices of upper leather, waxed
- 4 Prices extrapolated back from 1919 to 1916 by Canadian wholesale prices of harness leather
- 5 1922-23 prices obtained by computing an index of leather prices obtained from *The Economist*, "Commercial History and Review" The items used in the index are shoulders from dry salted hides, shoulders from wet salted hides, bellies from dry salted hides, and bellies from wet salted hides

APPENDIX C

NOTES TO TABLE C-8 (continued)

6. 1918-21 and 1923, see item 5.
14. 1916-17 and 1923, see item 5.
16. 1923 price is taken from 1923 price of item 1.
17. 1913 and 1923, see item 5.
22. 1884-89: Quantities obtained using prices from the Aldrich report—calfskins, tanned and dressed, French, J. Griffon and Co., for years 1885-89 and 1883. Prices were extrapolated back to 1884 by Aldrich report price for calfskins, tanned and dressed, French (E. Ogerau).
23. See item 22.
24. 1883 and 1889 prices extrapolated from Aldrich Report leather prices: calfskins, tanned and dressed, French, J. Griffon and Co.

028

Quarterly indexes are largely interpolated.

Items:

1. 1899-1913: Prices obtained by computing a fiscal year index for glove prices on a calendar 1913 base with imports-for-consumption unit values for gloves, Schmä-schen, of sheep origin, under 14", unlined; gloves, lamb, or sheep, "glacé" finish, not over 14", unlined; gloves, same as preceding description, piqué or prix seam; gloves, same, over 17", unlined; gloves, goat, kid, etc., "glacé" finish, not more than 14", unlined; gloves, same, piqué or prix seam, and gloves, same, over 17", unlined. Quarterly prices were obtained by a straight line interpolation.
- 1891-99: Quarterly prices used are interpolated freehand from an average of price relatives on a calendar 1899 base of imports-for-consumption fiscal unit values for gloves: "Schmä-schen," "Lamb or Sheep" and "Goat or Kid."

029

To a considerable extent, 1879-1918 based on outside price data. Quarterly indexes are largely interpolated.

Items:

10. 1919-23: Prices obtained by straight line interpolation of a calendar annual Fisher "ideal" index on a 1923 base for undressed furs. This index was computed from imports-for-consumption value and quantity data for fox, hare and rabbit, marten, mink, mole, muskrat, and squirrel.
- 1899-1913: Prices obtained by straight line interpolation of a calendar annual Fisher "ideal" index on a 1911 base for undressed furs. This index was computed from value and quantity data of Hudson's Bay Company fur sales for silver fox, white fox, lynx, marten, mink, land otter, and muskrat as given in J. W. Jones, *Fur-Farming in Canada* (Canada, Commission of Conservation, Ottawa, 1914). 1913 prices obtained by extrapolation.
- 1879-98: Prices obtained by interpolation of a calendar annual Fisher "ideal" index on an 1899 base using the same furs (excluding white fox) and the same source as for the 1899-1913 period.
11. Quarterly prices of "001 H hair, best," from WIB Price Bulletin No. 27, *Prices of Hatter's Fur and Fur Felt Hats* for 1913-18. The 1923 figure obtained by extrapolating above to 1919 by import unit values of "furs, undressed total" (1919 and 1918 third and fourth quarters) and to 1923 by the fur price index used for item 10.
12. Weighted average of price relatives of Canadian wholesale prices for mink, weighted once, and muskrat, weighted twice.

031

To a considerable extent, 1899-1911 based on outside price data.

Items:

1. 1912-23: Prices are Union of South Africa export unit values for ostrich feathers

APPENDIX C

NOTES TO TABLE C-8 (continued)

taken from reports of the Customs and Excise Department and converted to dollars

- 13 1899-1911 Same as for item 1, and for earlier years, similar records of the Cape of Good Hope, published in the *Government Gazette*

032

To a considerable extent, 1913-17 based on outside price data

Item

- 2 Price for last half of 1918 extrapolated back through 1913 by WIB price of West Australia pearl shells

036

The period 1892 and first half of 1893 based on outside price data

Item

- 10 1892 and first half of 1893 prices obtained by interpolating between fourth quarter 1891 and third quarter 1893 by BLS Para Island rubber prices. These prices were multiplied by the published quantity figures to obtain new values. The adjustment of values for this period was made in order to correct for a depreciation in the value of Brazilian paper money not reflected in the published values (see *Foreign Commerce and Navigation of the U S*, 1893)

039

To a considerable extent, 1894-1906 based on outside price data

Items

- 6 and 7 Unit values interpolated between 1917, third quarter and 1919, second quarter, by Italian olive oil price (*Annuario Statistico Italiano*)
17 22, and 23 Quarterly prices are U K prices of palm oil, Lagos, from *The Economist*
24 1894-99 Prices obtained by extrapolating the fiscal 1893 unit value by U K price of palm oil, Lagos, from *The Economist*
1899-1905 See item 17

040

The years 1879-83 based on outside price data

Item

- 30 Prices for 1879-83 are Aldrich report price for opium

041

To a considerable extent, 1891-99 based on outside price data. In the same period, quarterly indexes are largely interpolated

Items

- 21 Price used is Bezanson price for cutch 1891-96, extrapolated to calendar 1899 by imports-for consumption unit value of copal, damar, and kauri. Prices for 1897-98 are interpolated on a straight line between 1896, fourth quarter, and 1899
22 Prices for 1890 and 1889 are Bezanson prices for cutch. 1899 price is assumed to be the same as for item 21

044

Based to a considerable extent on outside price data. Quarterly indexes are largely interpolated

Items

- 2 1918-23 Prices are a quarterly Laspeyres index computed from prices for bergamot, cassia, citronella, orange, lavender, and spike lavender taken from *Perfumery and Essential Oil Record (Supplement Market Prices)*, New York, and weights taken from 1923 values given in imports for consumption

APPENDIX C

NOTES TO TABLE C-8 (continued)

1913-17: Prices are a quarterly Laspeyres index computed from WIB prices for oils of bergamot, cassia, orange, lavender, and rose, linked to 1923 and weighted by 1923 imports-for-consumption values.

3. Prices are a fiscal Laspeyres index on a calendar 1913 base computed from imports-for-consumption unit values for oils of bergamot, cassia, citronella, lavender, and rose, and weighted by imports-for-consumption values. Quarterly prices obtained by straight line interpolation.
4. 1884-1909: Same as item 3 except that lemon and orange have been included in the index.
7. 1879-83: See item 3.
8. 1879-83: Bezanson price for lemon oil.

047

Items:

1. 1917, third and fourth quarters, 1918, and 1919, first quarter, extrapolated by U.K. prices for cotton cloth, 38 in. shirtings, taken from *The Economist*.
7. 1899-1913: Fiscal year Fisher "ideal" index on a calendar 1913 base, using U.S. imports-for-consumption data for cotton pile fabrics: dyed, colored, stained, painted or printed; not bleached; dyed, etc.; all on which duty does not amount to 40-47.5 per cent; corduroy weighing 7 oz. or over per sq. yd. Quarterly prices estimated by straight line interpolation. Values for 1899-June 1906 were obtained by finding the ratio for each fiscal year of "cotton pile fabric" (imports-for-consumption value) to "all other manufactures of cotton" (general imports value) and assuming that the ratio remained constant for the four quarters within each fiscal year.
- 1891-99: Quarterly prices obtained by straight line interpolation of fiscal imports-for-consumption unit values for total cotton pile fabrics. Values obtained as for the 1899-June 1906 period.
8. 1913-June 1918: Prices used are BLS quarterly prices of "cotton thread, J. & P. Coats, 200 yd. spools."
9. 1914-June 1918: Values were calculated from quarterly figures for "total knit goods, cotton, excluding hosiery," using fiscal imports-for-consumption ratios of "gloves, cotton" to total "knit goods, cotton, excluding hosiery."
- 1914-16: Quantities obtained by straight line interpolation of fiscal imports-for-consumption unit values for "cotton gloves."
- 1920: Prices affected by shift from Japanese to German gloves during 1920. We estimated the annual price by extrapolating from 1921 by the import unit value from Germany alone, and interpolated the quarterly unit values by using those for hosiery.
31. 1902-09: Prices are BLS quarterly prices for "hosiery: cotton, women's mercerized 200 needle seamless, 50/2 yarn in leg, 30/2 yarn in heel and toe, 8/1 C.P., double sole and spliced heel, 8½-10, all colors, f.o.b. mill."
- 1898-1901: Prices are BLS annual prices for hosiery (see 1902-09 above) interpolated freehand to obtain a quarterly price series.
- 1893-97: Prices are BLS annual prices for hosiery (same as above) assuming quarterly prices are identical with annual.
- 1891-92: Quantities computed by extrapolating 1893 BLS price back by imports-for-consumption unit value for stockings valued at \$.60-\$2.00.

048

Item:

1. 1913-23: Quarterly unit values interpolated freehand from a Fisher "ideal" Index for jute and jute butts on a calendar 1923 base using U.S. imports-for-consumption data. British quarterly and annual wholesale prices of "jute, native firsts" from *The Economist* and U.S. quarterly and annual import unit values for "jute and jute butts" were used as guides in the interpolation.

APPENDIX C

NOTES TO TABLE C-8 (continued)

1901-13 Quarterly U. K. wholesale prices of "jute, native firsts" from *The Economist*

1899-1900 Prices extrapolated back to 1899 from 1901 annual price by French quarterly wholesale prices of "jute" from *La Réforme Économique*

1889-99 Quarterly unit values interpolated from a fiscal annual Fisher "ideal" index for jute and jute butts on a calendar 1899 base, using U. S. imports for consumption data. U. S. annual and quarterly import unit values for "jute and jute butts" and BLS annual and quarterly prices for "raw jute" were used as guides in the interpolation

049

Item

1 1889 Prices extrapolated by Bezanson prices for gunny cloth

1890-99 BLS series for jute

1899-1904 Unit values extrapolated back from 1905 by Canadian wholesale price of jute

051

Items

3 1913-23 Italian prices of hemp, 1914-23, from various volumes of *Annuario Statistico Italiano*, converted to dollars and extrapolated back to 1913 by United States import unit values

17 1879-83 Fisher "ideal" price index on a calendar 1889 base from imports for consumption data for jute, jute butts, and sisal, interpolated freehand

052

Items

1 Prices for 1919-23 extrapolated from 1918 unit value by imports for consumption unit values of "single yarns of flax, hemp, and ramie," interpolated freehand. Prices for 1913-14 extrapolated from 1915 import unit value by Canadian wholesale prices for "flax sewing twine"

2 Prices from 1899-1913 are general import unit values of "matting and mats of China, Japan and India straw" (item 2, class 053). For 1913-18 the same items are used to extrapolate from 1919

053

To a considerable extent, 1879-99 and 1922-23 based on outside price data. Quarterly indexes for 1899-1902 are largely interpolated

Items

5 Quarterly British export unit values to U. S. of "linen piece goods," converted to dollars

29 Fiscal imports-for consumption unit values of "plain-woven fabrics of vegetable fiber," interpolated freehand

30 Quarterly British export unit values of "jute piece goods"

31 Quarterly British export unit values of "linen piece goods, plain, bleached or unbleached"

34 1884-89 Quarterly British export unit values of "jute piece goods"

35 Quarterly British export unit values of "jute piece goods"

37 and 39 Quarterly British export unit values of "linen piece goods, plain, bleached or unbleached"

054

Item

2 The sudden spurt in imports of "clothing wool" in the second quarter of 1897 was in anticipation of the imposition of a ten cents per pound (over 60% ad valorem) tariff in July 1897. Imports fell off sharply immediately afterwards

APPENDIX C

NOTES TO TABLE C-8 (continued)

055

Quarterly indexes for 1913-June 1915 are largely interpolated.

Item:

1. 1913-June 1915 prices are interpolated from imports-for-consumption fiscal unit values of "woolen yarns."

056

To a considerable extent, 1879-99 based on outside price data.

Items:

4. 1879-89: Aldrich prices for "suitings, flannel; all wool, indigo blue, 6-4 Assabet." A few slight adjustments were made on these prices to make them conform better to imports-for-consumption unit values of "wool cloth."
- 1889-99: Annual U.K. export unit values of "worsted tissues, coatings, broad, all wool," other than to U.S., interpolated freehand, using as a guide, quarterly U.K. export unit values of "worsted tissues," other than to U.S.
5. 1899-1901: Prices obtained by extrapolating 1902 unit values back by quarterly U.K. export unit values of "worsted stuffs, mixed."
6. 1879-99: Quarterly U.K. export unit values of "carpets, not being rugs," other than to U.S.
9. 1914-June 1918: Fiscal import-for-consumption unit values of "woven fabrics, wholly or in chief value of mohair, alpaca, etc," interpolated freehand.

059

To a considerable extent, 1879-1913 based on outside price data. Quarterly indexes for 1913-18 are largely interpolated.

Items:

1. 1913-18: Unit values extrapolated back from 1919 by imports-for-consumption unit values of "total silk fabrics, woven in the piece, etc." Quarterly unit values were obtained by freehand interpolation using WIB quarterly price series for "imported broad silk, Japanese habutai, 3½ momme, 36" wide" and "imported broad silk, Japanese habutai, 6 momme, 36" wide" as guides.
- 1879-1913: Quarterly prices are interpolated from annual French export unit values for "tissus de soie pure, unis," Commerce Spécial, in *Annuaire Statistique*, Bureau de la Statistique Générale, and Direction Générale des Douanes, *Tableau Général du Commerce et de la Navigation*. All of these French export unit values are open to considerable suspicion because they are official, rather than declared, values (R. G. D. Allen and J. Edward Ely, *International Trade Statistics*, New York, 1953, pp. 94, 354-355). However, they were revised annually, and did not show the sudden large jumps which are characteristic of official values when revised only occasionally. We compared them with other series, such as those for average export given in Lyons, Chambre de Commerce, *Compte Rendu de Lyons*, and fragmentary U.S. imports-for-consumption unit values, and found them fairly similar.
4. 1879-1913: Quarterly prices are interpolated from annual French export unit values for "rubans de soie ou de bourre de soie pure, autre". See item 1, 1879-1913 for source.
7. 1879-1913: Quarterly prices are interpolated from annual French export unit values for "Passenterie de soie ou de bourre de soie pure." See item 1, 1879-1913 for source.

062

To a considerable extent, 1889-94, 1899 based on outside price data. Quarterly indexes for 1883-99 are largely interpolated.

Items:

9. 1883-99: Fiscal year prices were obtained by using imports-for-consumption quantity figures for "waste and other paper materials, including all grasses,

APPENDIX C

NOTES TO TABLE C-8 (continued)

- fibers, waste, etc., fit only to be converted into papers" and general import value figures for "paper stock, all other " Quarterly prices were obtained by freehand interpolation from fiscal year prices
- 20 1890-94 and 1899 Prices used are quarterly Canadian wholesale prices of "New Brunswick merchantable spruce deals "
- 1889 Annual price obtained by extrapolating back from 1890 by Canadian export price index for lumber (*Statistical Contributions to Canadian Economic History*, Vol II, by K W Taylor and H Michell)
- 063
- Items
- 5 1913-18 and 1923 Fisher "ideal" index using imports-for-consumption data for "cork, bark or wood, unmanufactured" and "cork waste and shavings, etc," interpolated freehand
- 9 1899 June 1909 Estimated quarterly values for "laths" (obtained by using the imports for-consumption ratio of "laths" to "all other lumber, dutiable,") have been subtracted out of "all other lumber, dutiable "
- 064
- To a considerable extent, 1899-June 1909 based on outside price data
- Item
- 1 1899-June 1909 See item 9, class 063 for method of obtaining quarterly values for "laths " Prices are quarterly Canadian wholesale prices of 'lath No 1 white pine, 1½ inch," adjusted to level of fiscal 1910 U S import unit value of "laths "
- 065
- Quarterly indexes for 1899-1908 are interpolated
- Item
- 8 1899-1908 and 1913 Quarterly prices were obtained by freehand interpolation of a fiscal Fisher "ideal" price index on a calendar 1913 base for imports-for consumption quantities and values of "wood pulp, mechanically ground," "wood pulp, chemical, bleached," and "wood pulp, chemical, unbleached "
- 066
- Quarterly indexes for 1899-1913 are largely interpolated
- Items
- 2 Prices extrapolated back from 1914 by quarterly Canadian wholesale prices of "wrapping paper, manila #1 "
- 11 1910-13 Quarterly prices were interpolated from annual German export unit values for "photographic paper, sensitized #663" taken from various years of *Statistik des Deutschen Reichs*, Statistisches Amt
- 17 1913 Annual price obtained by extrapolating from fiscal 1911 general import unit value for "total printing paper" by Fisher "ideal" price index for "printing paper," computed from general import values and quantities for "news-print" and "other printing paper "
- 20 1909 Same as for item 21 except that index was computed excluding "printing paper, valued above 5 cents per pound "
- 21 1905-08 Quarterly prices were interpolated freehand from a Fisher "ideal" fiscal price index for paper computed on a calendar 1913 base using imports-for consumption values and quantities for "copying, stereotype paper, etc , less than 6 pounds," "copying, stereotype paper, etc , 6-10 pounds," "crepe and filtering paper," "photographic paper, plain basic," "printing paper, valued above 5 cents per pound," and "surface coated paper, other n s p f "
- 23 1899-1904 Same as for item 21
- 25 1899-1913 Quarterly prices for 1910-13 were interpolated freehand from a Fisher fiscal price index on a calendar 1913 base using imports-for-consumption

APPENDIX C

NOTES TO TABLE C-8 (continued)

data for "articles lithographically printed: not exceeding $\frac{1}{16}$ inch in thickness, not exceeding 35 square inches, die cut or embossed, exceeding 35 square inches, and exceeding $\frac{1}{16}$ inch in thickness;" "souvenir postcards, lithographically printed: exceeding $\frac{1}{16}$ inch, and not exceeding $\frac{1}{16}$ inch in thickness, die cut or embossed;" "decalcomanias, in ceramic colors, not over 100 lbs.;" "booklets decorated in whole or in part by hand or by spraying;" and "booklets, all other."

Quarterly prices for 1899-1909 were interpolated freehand from a Fisher "ideal" fiscal price index on a calendar 1913 base, using imports-for-consumption values and quantities for articles lithographically printed (first four items listed above for 1910-13 index)—the index being adjusted to the level of the 1910-13 index.

072

To a considerable extent, 1899-1918 based on outside price data.

Items:

1. 1914-18: Prices obtained by extrapolating 1919 U.S. import unit value back to 1914 by quarterly South African export unit values of diamonds taken from *Trade of the Union of South Africa* (Union of South Africa, Customs and Excise Department).
 5. 1913, 1923: Quarterly prices for 1913 are South African export unit values of diamonds. 1923 annual price was obtained by extrapolating the fiscal 1919 South African export unit value of diamonds, by U.S. import unit value of "diamonds, rough, uncut" (item 1) for fiscal 1919 and calendar 1923.
- 1899-1913: South African export unit values for diamonds (see item 1 for source).

073

Based to a considerable extent on outside price data.

Items:

1. 1913-18: Quarterly prices prior to July 1918 obtained by extrapolation of unit values from calendar year 1919 by South African export unit values of diamonds (see Import Class 072, Item 1 for source).
- 1898-99: Quarterly prices are South African export unit values of diamonds (source same as for 1913-18).
11. 1898-99: See item 1, 1898-99, above.
13. 1897: Prices used are quarterly export unit values of diamonds exported from Kimberly division, taken from *Statistical Register*, Cape of Good Hope, Colonial Secretary's Dept.
16. 1884-96, 1899: See item 13.
- 1879-84: Annual prices extrapolated back to 1879 by obtaining export unit values from figures for values of diamonds exported through Customs and Post Office and quantity of diamonds exported through Post Office at Kimberly, taken from the *Blue Book*, Cape of Good Hope.

074

Items:

1. 1907-June 1908: Fiscal prices extrapolated back from 1909 by imports-for-consumption unit value of "asbestos, unmanufactured". Quarterly prices obtained by freehand interpolation.
- 1922 (fourth quarter)-1923: The sum of imports-for-consumption value figures for "Keene's cement or other gypsum cement, the same valued at: \$14 or less per ton, over \$14 and not over \$20 per ton, and over \$20 and not over \$40 per ton," have been subtracted from general imports, and new quarterly values estimated for 1923.
10. 1922 (fourth quarter)-1923: Quarterly values estimated from imports-for-consumption annual values for "lithographic stones" and general imports quarterly values for "other stones."

APPENDIX C

NOTES TO TABLE C-8 (continued)

- 15 1922 (fourth quarter)-1923 Quarterly values estimated from imports-for-consumption annual value for "fluorspar" and general imports quarterly values for "other nonmetallic minerals, dutiable"

075

Quarterly indexes are largely interpolated

Items

- 1 1916-23 Quarterly prices interpolated freehand from an annual price index on a calendar 1923 base obtained by computing an unweighted average of price relatives of silicon carbide, aluminum oxide, and metallic abrasives, taken from U S Bureau of Mines, *Minerals Yearbook*
- 5 1879-1918, 1923 Quarterly prices interpolated freehand from U S imports-for-consumption unit values of "marble veined and all other, in block, rough, or squared" (1879-83), "marble in block, rough or squared only" (1884-99), "marble, breccia, and onyx in block, rough, or squared only" (1899-1907), and "marble, breccia and onyx, total" (1908-18)

076

To a considerable extent, 1899-1923 based on outside price data

Items

- 1 1914-23 Prices are U K. quarterly export unit values (converted to dollars) of "jet, Rockingham, samian, and all other glazed earthenware, excl terra cotta"
- 2 1914-23 Prices are U K. quarterly export unit values (converted to dollars), of porcelain, chinaware, and parian
1914-first half 1915 Quarterly values estimated from total quarterly values for "china, parian and porcelain, decorated and not decorated" and from fiscal year totals of general imports from the U K. taken from *Annual Report of the Commerce and Navigation of the U S*
- 1922 and 1923 (fourth quarter) Quarterly values obtained by adding quarterly general imports for "china and porcelain" and estimated quarterly values of imports from U K. of "bisque and parian" (obtained by using annual figures from *Annual Report of Commerce and Navigation* of imports from U K. and quarterly figures for total imports)
- 3 1898-99 Prices are U S import unit values of "glass-cylinder and crown, polished, unsilvered" multiplied by the ratio of 1897 unit value of "cylinder and crown, polished, unsilvered" to the 1897 unit value of cylinder and crown, polished, silvered
- 23 1923, 1908-13 Prices are quarterly British export unit values of "floor tiles for tessellated pavement."
1904-07 1908 prices extrapolated back by quarterly British export unit values of "other earthenware, incl semi porcelain, majolica, and tiles"
1899-1903 1904 prices extrapolated back by quarterly unit values of U S imports of "china, parian, porcelain, etc., from U K." (see item 24 for source of prices)
- 24 1908-13 Prices are U K. quarterly export unit values of "other earthenware, incl semi porcelain and majolica."
1904-07 1908 prices extrapolated back by U K. quarterly export unit values of "other earthenware, incl semi porcelain, majolica, and tiles"
1899-1903 1904 prices extrapolated back by annual German export unit values of porcelain ware, taken from *Greifswalder Staatswissenschaftliche Abhandlungen* 51, p 161-2 Quarterly prices obtained by interpolation

077

To a considerable extent, 1899-1903 based on outside price data

Quarterly indexes for 1899-93 are largely interpolated.

APPENDIX C

NOTES TO TABLE C-8 (continued)

Items:

3. 1894 (Sept.) and 1899 (fourth quarter), annual: Prices extrapolated by Canadian wholesale price of "copper, casting ingot" from eight-month period ending August 1894.
11. 1922-23: Prices extrapolated by BLS price for "zinc sheets" from 1921 annual U.S. import unit value.
19. 1899-1903: Prices extrapolated back from 1904 by U.S. import unit values of "unrefined copper."
1895-99: Prices used are U.S. import unit values of Import Class 078, item 24.
23. 1891-93: Prices used are interpolated freehand from a Fisher "ideal" price index on a fiscal 1895 base using imports-for-consumption data on "lead contained in silver ore" and "lead pigs and bars, etc."
24. 1889-90: Quarterly prices interpolated from imports-for-consumption fiscal unit values for "lead ore, pigs, bars, etc., excluding lead in silver ore."

078

Items:

8. 1922 (fourth quarter)-1923: Quarterly values and quantities estimated from general imports quarterly data for "platinum, unmanufactured" and imports-for-consumption data for platinum in ingots, bars, sheets or plate, not less than $\frac{1}{8}$ inch thick.
34. 1883-89: Quarterly quantities obtained by freehand interpolation of imports-for-consumption fiscal unit values for "lead, pigs and bars."

079

Items:

1. 1913, 1923: Quantities for 1913 obtained by interpolation of a fiscal 1913 and 1st quarter fiscal 1914 Fisher price index on a calendar 1923 base computed from U.S. imports-for-consumption values and quantities for watches "having not more than 7 jewels;" "having more than 11 and not more than 15 jewels;" "having more than 15 and not more than 17 jewels;" and "having more than 17 jewels."
3. 1899-1913: Same as item 1, except that index is on a fiscal 1913 base.

081

To a considerable extent, 1913-June 1916 based on outside price data.
Quarterly indexes for 1899-1913 are largely interpolated.

Items:

3. 1922 (fourth quarter)-1923: Quantities obtained by using British export unit values (converted to dollars) of "iron and steel and manufactures thereof; incl. pig iron and ferro alloys—ferro alloys including Spiegeleisen and ferro-manganese, etc."
1916 (first half): Prices are U.S. import unit values for six months ending June interpolated by U.K. export unit values (see above).
1913-15: Prices used are U.K. export unit values (see above) extrapolated from U.S. calendar 1916 import unit value.
5. Prices extrapolated back from calendar 1916 by U.S. quarterly wholesale prices of "basic pig iron" taken from WIB.
14. 1899-1913: Quarterly prices are interpolated from a fiscal Fisher price index on a calendar 1913 base computed with imports-for-consumption data on "ferro-manganese," "ferrosilicon," "Spiegeleisen" and "all other pig iron."

082

To a considerable extent, 1913-23 based on outside price data.
Quarterly indexes for 1889-1913 are largely interpolated.

APPENDIX C

NOTES TO TABLE C-8 (continued)

085

To a considerable extent, 1899-1913 based on outside price data.

Quarterly indexes for 1913-June 1918 are largely interpolated.

Items:

1. 1899-1913: Quantities obtained by using *Oil, Paint, and Drug Reporter* price quotations for fish guano (adjusted for changes in methods of quoting).
2. 1906-June 1911: Quarterly values estimated from "all other fertilizers" using imports-for-consumption values for "bone phosphates" to obtain fiscal year ratios. Quarterly quantities obtained by freehand interpolation of imports-for-consumption unit values for "bone phosphates."
3. 1913-June 1918: Estimates of quarterly values for "calcium cyanamid" have been subtracted out and imports-for-consumption unit values for "other fertilizers" have been interpolated freehand to obtain quarterly unit values.
5. 1910-13: Prices of kainite taken from *Oil, Paint, and Drug Reporter*.
1910-June 1911: Values estimated from imports-for-consumption values of kainite and general imports quarterly values of "kainite and manure."
7. 1910-13: Quarterly values estimated from general imports values for "other fertilizers" and imports-for-consumption fiscal values for "calcium cyanamid." Quarterly quantities obtained by freehand interpolation of imports-for-consumption unit values for "calcium cyanamid."
9. 1899-1909, 1913: Prices of kainite from *Oil, Paint, and Drug Reporter*.

086

Items:

2. 1913-June 1918: Quarterly values estimated from imports-for-consumption fiscal values for "calcium cyanamid" and general imports values for "other fertilizers." Quarterly quantities obtained by freehand interpolation of imports-for-consumption fiscal unit values for "calcium cyanamid."
6. 1899-June 1907: Quarterly values estimated from imports-for-consumption fiscal values for "dead or creosote oil" and general imports values for "mineral oil." Quarterly quantities obtained by freehand interpolation of imports-for-consumption fiscal unit values for "dead or creosote oil."
15. 1913-23: Quarterly quantities obtained by freehand interpolation of a Fisher "ideal" price index on a calendar 1923 base for fiscal years 1913-18 and calendar years 1919-22. The index was computed using imports-for-consumption values and quantities for "arsenic or arsenious acid," "phosphoric acid," "sulphuric acid," and "acetic or pyroligneous acid."
16. 1917-23: Quarterly quantities obtained by freehand interpolation of a Fisher "ideal" price index on a calendar 1923 base for fiscal years 1917-18 and calendar years 1919-22. The index was computed using imports-for-consumption values and quantities for "citric acid," "tartaric acid," and "boric (boracic) acid."
17. 1913-16: See item 16.
- 18 and 19: Before July 1916, U.S. import data did not separate natural from synthetic indigo although the latter was much cheaper. Since synthetic indigo did not drive the natural product completely out of the market, the two were treated here as separate commodities and it was therefore necessary to break down reported imports into the two types. The only data available for this purpose were the annual reports of imports by country of origin. Since synthetic indigo came mainly from Germany and to some extent from Switzerland, we took imports of indigo from these countries to represent imports of synthetic indigo and the rest to represent natural indigo. Quarterly imports were estimated by assuming that the ratio of synthetic to natural was constant throughout the year.
- 1913-June 1916: Quarterly prices of natural indigo were extrapolated back from fiscal 1917 by U.K. wholesale prices of "indigo, Bengal, good consuming," from *The Economist*. Quarterly prices of synthetic indigo were extrapolated back by WIB, "synthetic indigo."

APPENDIX C

NOTES TO TABLE C-8 (concluded)

1899-1913 Quarterly prices of natural indigo, 1901-13, are U K. wholesale prices of "indigo, Bengal, good to fine" from *The Economist* These were extrapolated back to 1899 by annual U K. wholesale prices of "indigo, Bengal, good consuming," from *The Economist* and interpolated freehand Synthetic indigo prices are from the *Oil, Paint, and Drug Reporter* quotations for "J (synthetic) indigo"

087

To a considerable extent, 1913-23 based on outside price data

Items

- 1 1913-23 BLS prices for "quinine sulphate"
- 4 1913-15, 1919-23 Quarterly prices obtained by freehand interpolation of imports-for-consumption unit values for "firecrackers"
- 5 1916-19 Quarterly prices obtained by freehand interpolation of imports-for-consumption unit values for "gunpowder, etc."
- 1920-23 Quarterly prices obtained by freehand interpolation of imports-for-consumption unit values for "fulminates"

Appendix D

Construction of Quarterly Interpolating Series for U.S. Department of Commerce Annual Import Price Indexes

THE indexes described here were computed to fill a gap in the quarterly import indexes between the end of the National Bureau's indexes in 1923 and the beginning of the official Department of Commerce indexes in 1929. On the export side, the gap is bridged adequately by Cowden's indexes, which are available monthly from 1923 through 1930.¹ For imports, the only series available were the annual Department of Commerce indexes and an inadequate monthly volume index published by the American Tariff League. We accepted the annual Commerce series and constructed quarterly series from them by interpolation. The interpolating series were quarterly and annual indexes constructed in such a way that the annual indexes closely matched the Commerce series.

The Commerce series are Fisher "ideal" price indexes, but, unlike ours, are constructed with constantly changing bases, the index for each year using the previous year as a base. The interpolating indexes we prepared are of the same type as the Commerce indexes, but we attempted to roughly duplicate the annual movements of the Commerce series with a smaller number of commodities. The two sets of annual indexes are shown in Table D-1.

The year-to-year changes in the two sets of indexes are very similar. Of thirty comparisons, twenty-five show either no difference or a difference of only one percentage point; only one discrepancy is as high as 4 per cent.

Because of the similarity of the two series we considered it safe to use a fairly crude method of interpolation. Each quarterly interpolating index was multiplied by the ratio, for that year, of the Commerce index to the annual interpolating index. The interpolated Commerce price indexes derived in this way, with 1923 equal to 100, are given in Table D-2.

We did not, in most cases, make any attempt to improve on the Commerce indexes. The published export and import values were used² without the introduction of outside price data which might have improved the coverage or representativeness of the indexes. All the series were examined, however, by comparing them with price data or by making country breakdowns.

	IV	128	54	83	96	87

Tables D-3 to D-7 show the list of commodities included in our interpolating indexes, the extent to which they cover the commodities in the Commerce indexes, and the extent to which they cover all of the commodities in each economic class. Notes to these tables indicate differences in composition between the Commerce indexes and ours and describe peculiarities and inadequacies in the individual commodity data.

TABLE D-3

B. as % of D	72.6	74.0	75.3	76.4	74.4	74.4	74.8

APPENDIX D

NOTES TO TABLE D-3

Commerce indexes include the following additional items:

1924-29: cream, fresh; milk, fresh; fresh water fish and eels; halibut, fresh or frozen; lobsters, not canned; beans, dried; potatoes, white or Irish; turnips; onions; grapes; coconuts in the shell; walnuts, not shelled; cloves, unground; pepper, unground, white.

1925-1929: smelts, fresh or frozen; tuna fish, fresh or frozen; tomatoes, natural state.

1926-1929: chestnuts.

Commerce excludes coffee from Venezuela and Mexico.

As indicated, the NBER indexes divide tea by country instead of using total tea as Commerce does. This was done because of large and persistent differences among teas imported from the three countries, apparently due to differences in grade or type of tea and possibly to differences in transport cost.

Unit values for bananas, which are used in both Commerce and NBER indexes, do not inspire much confidence. They remained quite stable from 1925 through 1929 while the BLS price series for bananas of a specific size and country of origin, at New York, fell by more than a quarter. Furthermore, the import unit values differ among themselves in both level and movement. There are several plausible explanations for these differences. A letter from the BLS suggests that changes in the unit value reflect changes in the average size of bunches of bananas, since prices are in terms of dollars per bunch. A letter from the Commerce Dept. points out this possibility and the additional fact that bananas imported from foreign branches or subsidiaries of American firms have often "been declared at arbitrarily fixed prices for a good many years."

Despite large differences in the levels of unit values, by country of origin, the total unit value gives a fairly good representation of the individual country unit value series.

TABLE D-4
VALUE OF COMMODITIES IN NBER INTERPOLATING INDEXES, MANUFACTURED FOODSTUFFS

B as % of D	81.2	79.9	71.2	70.9	73.6	69.7	69.3

APPENDIX D

NOTES TO TABLE D-4

Commerce indexes include the following additional items:

1924-29: beef, fresh; veal, fresh (beef and veal combined, 1924-25); butter; lobsters, canned; currants; dates; coconut meat, dessicated or prepared, free; coconut meat, dessicated or prepared, dutiable.

1925-29: egg yolk, dried; egg albumen, dried; tomato paste.

1929: pork hams; pork shoulders; bacon; herring, pickled or salted.

As indicated, NBER indexes separate cheese by country, whereas Commerce has a total cheese series.

Commerce separates wheat by-products into those of "direct importation" and those "withdrawn from bonded mills" for 1926-29; it uses the combined series only for 1924-25.

Commerce separates olive oil into "packages less than 40 lbs." and "packages 40 lbs. or over;" it separates free cane sugar from dutiable. We did not follow Commerce on this last breakdown because it is an artificial distinction created by the tariff act rather than one based on differences in the type or grade of commodity. The shift brought about by the tariff differential from lower priced (in country of origin) Cuban sugar to higher priced (in country of origin) Philippine sugar represented a rise in the price paid by the United States rather than a change in taste.

TABLE D-5
VALUE OF COMMODITIES IN NIER INTERPOLATING INDEXES, CRUDE MATERIALS
(in thousands of dollars)

	1923	1924	1925	1926	1927	1928	1929

B. as % of C.	1,407,000	1,502,487	1,550,906	1,257,495	1,351,774
B. as % of D.	90.4	1,747,233	1,600,809	1,466,733	1,558,620
	73.2	88.2	87.1	87.0	86.0
		73.5	75.5	74.6	74.6

Commerce includes the following additional items:

1924-29: Cattle hides, dry or dry-salted; kip skins, wet-salted; calf skins, wet-salted; horse, colt, and ass hides, wet-salted; bones, hoofs, and horns, unmanufactured; mother of pearl; chicle, crude; gum arabic or senegal; cinchona bark or other from which quinine may be extracted; pyrethrum flowers; licorice root; castor beans; sugar beet seed; bulbs, hyacinth; vegetable ivory; flax, unmanufactured, hacked; flax, unmanufactured, all other; hemp, unmanufactured; kapok; isle or tampico; logs of fir, spruce, or western hemlock; cork wood or bark, unmanufactured; pulpwood, rough; pulpwood, peeled; rags for paper stock; anthracite coal; bituminous coal; china clay or kaolin; pyrites or sulphide of iron; iron ore; manganese ore (dutiable); chrome ore or chromite; aluminum, bauxite, crude; copper concentrates; lead ore and matte; lead bullion and base bullion; nickel ore and matte; Kainite; manure salts. 1925-29: guano. 1927-29: platinum grains, nuggets, sponge, and scrap. 1928-29: furs, beaver. 1929: furs, fitch, kolinski; furs, weasel; carnauba wax.

NBER index includes only carpet, clothing, and combing wool on the skin or in the grease, 1925-29, while Commerce combines these with corresponding wools washed and scoured. In 1924, both series use the combinations. The NBER index separates carpet wool, free, from carpet wool, dutiable, throughout.

NBER uses raw silk from China and raw silk from Japan as separate commodities. Commerce uses total raw silk.

Instead of the division by country for crude petroleum, Commerce uses total crude petroleum throughout as does NBER for 1924-25. The total petroleum series was separated by country of origin, because the unit values moved very differently from changes in domestic petroleum prices and from several of the country import unit value series. It seemed possible that these differences could be caused by shifts among the sources of petroleum, since there were some substantial differences in the level of unit values that were at least partly due to differences in specific gravity.

APPENDIX D

NOTES TO TABLE D-6

Commerce includes the following additional items:

1924-29: potassium carbonate; potassium hydroxide (caustic potash); sodium cyanide; lithopone and zinc pigments, including zinc oxide and leaded zinc; ammonium sulphate; calcium cyanide; bone ash, dust, and meal; chloride of potash, crude; potassium sulphate, crude; sole leather; calf and kip upper leather; goat and kid leather; cod oil and cod-liver oil (combined, 1924-28 and separately for 1929); casein or lactarene; camphor, crude; quebracho extract; cotton yarns, bleached, dyed, etc.; wool noils; poles, telegraph, telephone, etc.; sawed boards and lumber, hardwood; cork waste and shavings; marble, onyx, and breccia, in blocks; cement, hydraulic; steel ingots; tinplate, terneplate and taggers' tin; antimony, liquidated, regulus; coal tar colors, dyes, etc.; arsenious or white arsenic; tartaric acid; argols and wine lees.

1925-29: potassium chlorate and perchlorate; olive oil, sulphured or foots.

1926-29: iodine, crude.

1927-29: calf and kip lining leather; glycerin, crude; ferromanganese and other manganese alloys.

1928-29: platinum ingots, bars, etc.

1929: perilla oil; asbestos, mill fiber; asbestos, stucco and other.

Commerce excludes the following items: bristles, sorted, bunched, or prepared; coconut oil, free; and rayon yarns, threads, or filaments.

TABLE D 7
 VALUE OF COMMODITIES IN NINE R INTERLATING INDEXES MANUFACTURED PRODUCTS
 (in thousands of dollars)

	1923	1924	1925	1926	1927	1928	1929

It as % of D	34.0	35.4	37.1	36.1	38.4	36.4	34.4

NOTES TO TABLE D-7

Commerce includes the following additional items:

1924-29: footwear with textile uppers, from Czechoslovakia; footwear with textile uppers, from Japan; camphor, refined, and camphor, synthetic (combined, 1924; separate, 1925-29); citronella and lemon grass oil; cotton sewing thread; cotton cloth, bleached; cotton cloth, printed, dyed, colored, etc.; jute bags or sacks; flax fabrics, 4 to 12 oz. per square yard; handkerchiefs, linen, not embroidered or of lace; handkerchiefs, of lace or embroidered; binding twine; wool hosiery; silk bolting cloths; silk pile fabrics; Kraft wrapping paper (combined with "all other wrapping paper" in 1924); pulp board in rolls; cigarette paper, books, etc.; plate glass; flat wire and steel strip n.e.s.; nails (nails and screws after 1925); electric lamps other than carbon; quinine sulphate; firecrackers; soap, castile; golfballs; other balls for games; watches and watch movements; tooth brushes.

1924-26: table damask and manufactures.

1925-29: geranium oil; worsted fabrics over 4 oz. per square yard; tracing cloths; menthol; soap, toilet.

1927-29: china and porcelain table and kitchen ware, domestic and household, from Germany; same, from Japan; earthenware crockery, and stoneware, table, toilet, and kitchen ware, domestic and household, from U.K.; same, from Japan; barbed wire; glycerine, refined.

Commerce excludes: cigars and cheroots, free; cigars and cheroots, dutiable.

The NBER index separated carpets and rugs from Persia and China because the increase in unit value of total carpets and rugs seemed to arise from a shift in type from Chinese and other lower priced rugs to the more expensive Persian rugs.

Cotton cloth was omitted from the NBER interpolating index because the import unit values, even those for imports from the U.K. alone, moved so differently from both U.S. and U.K. prices, and because there were such large differences among the import unit value changes for the various countries of origin.

Silk fabrics, broad, except pile fabrics were not used in the NBER index because the steep decline in their unit values would have caused the index to fall steadily relative to the Commerce index. On the other hand, gasoline, naptha, etc. were added to the NBER index, despite great disparities in the unit value movements of the country-of-origin components, and between the total and the components, in order to give the interpolating series a shape closer to that of the Commerce index.

We omitted watches and watch movements from the NBER index because our study of the earlier data showed that quality changes were often the predominant causes of the unit value changes in the total group.

It is clear that the index for this group is the least satisfactory of the five. The coverage is low, never rising above 40 per cent, and more than half of the coverage is provided by two items, burlap and newsprint, which could be considered semimanufactures, and were in fact removed from the manufactured group in the Federal Reserve Bank study, *The Pattern of United States Import Trade Since 1923*, by John H. Adler, Eugene R. Schlesinger, and Evelyn Van Westerborg.

Appendix E

Data on Variability, Sampling Error, and Coverage

The first part of this Appendix presents the basic data on the variability of price movements within and among minor classes and estimates of sampling error for minor and major classes. The second contains detailed information on coverage and shifts in coverage.

VARIABILITY AND SAMPLING ERRORS

Two assumptions must be kept in mind as the basis for these measurements and their interpretation. One is that the commodities which are covered in the minor class indexes are completely covered—the prices for individual commodities are assumed to be known precisely and not subject to sampling error. The other is that commodities and minor classes have been selected for the sample randomly, either with equal probabilities or with probability proportional to size.

Table E-1 gives weighted and unweighted standard deviations for minor classes where they were computed. They could not be calculated for uncovered classes or for classes in which there was only one covered commodity. The latter are divided into two groups: those with only one commodity, for which, by our assumption, there is no variance, and those with one covered commodity and one or more uncovered ones, for which we cannot measure the variance. These standard deviations are measures of the homogeneity of classes rather than of the accuracy of the indexes, although homogeneity does, of course, affect accuracy. They are descriptive of the covered commodities within each class and do not require any assumption of randomness in the sampling procedure. A large standard deviation implies a heterogeneous stratum but it may not, if coverage is high, imply inaccuracy in the estimation of the mean. The two standard deviations in Table E-1 are

$$\text{Unweighted } \sigma_u = \sqrt{\frac{\sum \left(\frac{P_1}{P_0}\right)^2}{N} - \left(\frac{\sum \frac{P_1}{P_0}}{N}\right)^2}$$

$$\text{Weighted } \sigma_w = \sqrt{\frac{\sum P_0 Q_0 \left(\frac{P_1}{P_0}\right)^2}{\sum P_0 Q_0} - \left(\frac{\sum P_1 Q_0}{\sum P_0 Q_0}\right)^2}$$

The σ_u is appropriate for an unweighted index or for an assumption that the commodity weights among the covered items are irrelevant to the uncovered ones, that is, each commodity, no matter how large, is only a

single observation of the mean. The weighted standard deviation is appropriate for use with a weighted index and, in general, for the assumption that the importance of different price behavior patterns in the uncovered items would match that among the covered commodities. Equality of the two standard deviations implies no correlation between the weight or importance of a commodity and its distance from the mean. The usual case—namely that σ_u is greater than σ_w means that the correlation is negative; and σ_w greater than σ_u implies that the importance of a commodity is positively correlated with exceptional behavior (distance from the mean).

Standard errors of the mean (the mean being the Laspeyres price index) are given in Table E-2. These do involve inference from the standard deviations. They are measures of the accuracy of the minor class indexes, under the assumption that the commodities sampled are representative of all commodities in their groups. In other words, samples are treated as if they had been drawn randomly. Since only the weighted standard errors are shown here, the assumption implied is that the sample was drawn with probability proportional to size (value) rather than, as in the unweighted indexes, equal probability of representation for each commodity.

Two sets of standard errors are computed. The first, with no finite sampling adjustment, takes account of the number of commodities drawn from each class but not of the proportion of total value covered. It treats the samples as if they included only a small part of the whole class. It answers the question, "How accurate an estimate of the mean could be made with a sample of this size from a large population?" The second set takes account not only of the number of items but also of their share in the total value of the class. It makes use of the fact (or assumption) that the mean is known precisely for a substantial part of the total (the sample) and that, in effect, the estimation applies only to the remaining, often small, fraction of the total value.

The two measures of standard error can be described in terms of the standard deviations of Table E-1, where N is the number of covered commodities in the minor class.

Without finite sampling adjustment:

$$\sigma_m \text{ (unadjusted)} = \frac{\sigma_w}{\sqrt{N-1}}$$

With finite sampling adjustment (where f is the coverage ratio):

$$\sigma_m \text{ (adjusted)} = \frac{\sigma_w}{\sqrt{N-1}} \sqrt{1-f}$$

APPENDIX E

Coefficients of variation presented in Table E-3, are the ratios of standard errors to the means they apply to. In this case the means are the Laspeyres price indexes. Only the weighted measures are shown, but the relationship between weighted and unweighted coefficients would be the same as in Table E-1.

The variance of a major class mean can be calculated from the variance within minor classes (already computed) and the variance among minor classes, as follows:

$$Var_{\bar{x}} = \frac{1}{n-1} \left[\left(\frac{V-v}{V} \right) \sum_{i=1}^n \frac{V_i (\bar{x}_i - \bar{x})^2}{v} + \sum_{i=1}^n \frac{1}{m_i} \cdot \frac{V_i}{v} \left(\frac{V_i - v_i}{V} \right) S_i^2 \right]$$

where

n = number of sampled minor classes

N = number of minor classes

m_i = number of sampled commodities in minor class i

M_i = number of commodities in minor class i

V_{ij} = value of commodity j in minor class i

v_i = value of sampled commodities in minor class $i = \sum_{j=1}^{m_i} V_{ij}$

V_i = value of all commodities in minor class $i = \sum_{j=1}^{M_i} V_{ij}$

v = value of sampled minor classes = $\sum_{i=1}^n V_i$

V = value of all minor classes = $\sum_{i=1}^N V_i$

\bar{x}_{ij} = value of price relative for commodity j in minor class i

\bar{x}_i = means of minor class $i = \sum_{j=1}^{m_i} \frac{V_{ij} \bar{x}_{ij}}{v_i}$

\bar{x} = major class mean = $\sum_{i=1}^n \frac{V_i \bar{x}_i}{v}$

S_i^2 = minor class variance = $\frac{1}{v_i} \sum_{j=1}^{m_i} V_{ij} (\bar{x}_{ij} - \bar{x}_i)^2$

The S_i^2 is the square of the weighted standard deviation of Table E-1

These computations are carried out in Table E-4 and the coefficients of variation derived from these variances are shown in Chapter 5, Table 18.

MEASURES OF COVERAGE AND CHANGE IN COVERAGE

Tables E-5 through E-8 give basic data on coverage for all major and intermediate classes. The figures show, for the earliest year of each period, the ratio of the value of covered commodities to the value of all commodities in the class. For the last year of each period they show the ratio of the value of those commodities which were covered in the first year to the value of all the commodities which were part of the class in the first year. Thus, for within-period comparisons, changes in coverage due to increasing availability of data are eliminated.

For each period, the table reveals whether the commodities covered in the initial year grew in value at a faster or slower rate than the uncovered ones. In order to see the trend of coverage as a whole (not just that for fixed groups of commodities) one must follow the movement from the right-hand column of one period to the right-hand column of the next. Export Class 115 in Table E-5 illustrates the two uses of the table. By 1889, the commodities covered in 1879 had fallen from 91 to 89 per cent of the total value of the class. But those commodities which actually were covered in 1889 formed 97 per cent of the total value of the class in that year.

It should be noted that these tables show the proportion of total value in covered commodities, not that contained in covered minor classes. These changes in coverage do not indicate the possibility of bias in the total or major class indexes, because they include the effects of both shifts in the weight or importance of minor classes and shifts within them. Only the latter, as is pointed out in Chapter 5, would suggest bias because they indicate that covered commodities possessed different characteristics (possibly different price changes) from uncovered products. Tables E-9 through E-12 are intended to reveal such shifts. They show the actual end-year coverage ratios for commodities covered in the initial year (first columns of Tables E-5 through E-8) as percentages of the ratios that would have existed if values of covered and uncovered items had grown at the same rate within each minor class.¹ Thus, a ratio over 100 per cent indicates that covered commodities grew at a more rapid rate than uncovered commodities.

¹ The computation of the hypothetical ratios is performed by applying the initial year coverage ratio to the end-year value for each minor class.

Appendix F

Adjustments for Changes in the U.S. Customs Area

THE incorporation of Hawaii and Puerto Rico into the United States customs area in 1900 introduced a degree of incomparability into the official foreign trade records. The official figures, which include the effect of the annexations, are appropriate for the calculation of the balance of payments but not for the comparison of foreign trade with domestic prices and production.

The only way to achieve consistent territorial coverage would have been to include or exclude Hawaii and Puerto Rico for the entire period studied, but this would have been too laborious. Instead, we only included the two territories back through 1899. This made the 1899-1913 period internally consistent and provided an overlap in 1899 to which the earlier data excluding the two possessions could be spliced.

Recalculating the value of trade involved the subtraction from the published data for the United States of the trade of Puerto Rico and Hawaii with the United States, and the addition of the trade of the two territories with the rest of the world. This computation is described in detail in Table F-1.

The change in total exports and imports is small. For exports, it was 6/10 of one per cent in calendar years 1899 and 1900 and no higher than 1.3 per cent in any quarter, for imports it was 2.3 per cent in calendar 1899 and 1 per cent in calendar 1900, the greatest change being 3.7 per cent in one quarter.

Imports into Puerto Rico and Hawaii were scattered widely over the commodity list but exports from them were extremely concentrated. Almost all their exports were accounted for by green coffee from Puerto Rico and sugar from both territories, most of the latter was exported to the United States. As a result of this commodity concentration the effect of the adjustment is almost entirely on two of our minor classes, Export Class 004 (green coffee) and Import Class 019 (sugar and related products, agricultural).

Since all U.S. exports of green coffee were from Puerto Rico, Export Class 004 was empty before July 1900 in the official records. Furthermore, because no commodity data were used for parts of years in which data for the full year were not available, the recorded exports of green coffee for the last half of 1900 were thrown into 'all other articles.' The inclusion

of Puerto Rico makes it possible to carry this class back to 1899, as is shown in Table F-2. Only one price index is given because this is a one-commodity class. All indexes are reduced to the ratio of the given year price to the base year price.

The adjustments in Export Class 004 require some changes in the intermediate and major classes of which it is a component. These are shown in Tables F-3 and F-4. Adjustments in the price index were carried through Export Class 205; after that they were negligible and only the quantity indexes and dollar values were altered.

On the import side, shifting Puerto Rico and Hawaii across the customs frontier lowered the price, quantity and value indexes for Import Class 019 to the levels given in Table F-5. The reductions in 1899, the only year in which all four quarters were affected, were about 9 per cent in price, 15 per cent in quantity, and 23 per cent in value.¹

As these changes were carried into the intermediate and major classes (see Table F-6) the reduction in the price index for Import Class 019 tended to lower the indexes for the classes into which it was combined. In addition, the adjustments lowered quantities and values for Class 019 and therefore reduced its weight in these combinations. Since the 1899 price index for this class was high compared with those of the classes with which it was combined, its loss of weight further lowered the price indexes for combined groups.

Table F-7 gives adjusted and unadjusted quantity indexes for total exports and imports. The adjustment in the export index reflects only changes in the value series while that in imports reflects changes in the price index as well.

¹ The eliminated Hawaiian and Puerto Rican sugar imports had much higher average unit values than those from all other countries, 59 per cent higher in fiscal 1899 for example (*Foreign Commerce and Navigation of the United States*, 1899, Vol. II, pp. 366-368). Most of this was duty-free sugar from Hawaii, with an average unit value of 3.7 cents per pound in 1899. The average unit value for dutiable sugar was 2.2 cents per pound and the duty on it was 1.7 cents.

APPENDIX F

NOTES TO TABLE F-1

* From various issues of U.S. Treasury Department, Bureau of Statistics, *Monthly Summary of Commerce and Finance of the United States*, 1899, 1900, and 1901.

^b July 1899 to April 1900 from U.S. Customs and Insular Affairs Division, *Monthly Summary of Commerce of the Island of Puerto Rico*. Calendar year 1899 and Jan. to June 1900 totals including coin and bullion, from the *Statistical Abstract of the United States*, 1906, p. 487, were used, after adjustment for gold and silver imported and exported July 1899-April 1900, to estimate the remaining quarters. Therefore the figures for Jan. to June 1899 and May and June 1900 may include some coin and bullion. The Jan. to June 1899 total for exports was distributed between the two quarters in the same proportion as exports of green coffee (see Table F-2); for imports—the same proportion as U.S. exports to Puerto Rico (See col. 2).

^c Calendar 1899 and Jan.-June 14, 1900 totals from the *Statistical Abstract of the United States*, 1906, p. 488, were distributed for exports among the quarters in the same proportions as imports, col. 3, and for imports, in the same proportion as exports, col. 3.

IV	26	91.614	1.376	1.261
Calendar Year	1,185	85.669	16.524	14.156

SOURCE: Data are from various issues of U.S. Customs and Insular Affairs Division, *Monthly Summary of Commerce of the Island of Puerto Rico*. Figures for May and June 1899 include exports to the U.S., but these were assumed to be small since U.S. imports of coffee from Puerto Rico were only \$222,000 during the whole of fiscal 1899. We estimated figures for the second quarter of 1900 by multiplying the April values and quantities by three.

APPENDIX G

NOTES TO TABLE G-1

SOURCE Columns 1 and 3 Theodore J Kreps, "Export and Import Prices in the United States and the Terms of International Trade, 1880-1914," *Quarterly Journal of Economics*, August 1926, p 714 We converted the Kreps index from fiscal 1903-13 = 100 to calendar 1913 = 100, estimating calendar 1913 as the average of fiscal years 1913 and 1914

Columns 2 and 4 Table A-24, Export Class 220, and Table A-25, Import Class 221. Fiscal year indexes are unweighted averages of four quarterly figures.

1912	96.4	96	99.5	98
1913	100.0	100	100.0	100

SOURCE: Columns 1 and 3: Albert H. Imlah, *Economic Elements in the Pax Britannica*, Cambridge, 1958, pp. 96-98. We converted Imlah's index from 1880 = 100 to 1913 = 100.

Columns 2 and 4: Charles P. Kindleberger, *The Terms of Trade: A European Case Study*, New York, 1956, pp. 22-25. The current account indexes were adjusted as indicated in the source to calculate the commodity trade indexes. The Schlote indexes were taken from this source to insure their comparability with the indexes for industrial Europe in Table G-4. They were originally published in Werner Schlote, *British Overseas Trade from 1700 to the 1930's*, Oxford, England, 1952.

APPENDIX G

NOTES TO TABLE G-9

- SOURCE: Column 1, 1956-60: *Survey of Current Business*, July 1961, p. 32.
 1910-55: *Ibid.*, October 1958, p. 13.
 1869-1909: Extrapolated from 1910 by Frederick Strauss and Louis H. Bean, *Gross Farm Income and Indices of Farm Production and Prices in the United States, 1859-1937*, U.S. Dept. of Agriculture, Technical Bulletin No. 703, p. 24, Table 8, column headed "Total (gross income) adjusted for changes in inventory values of meat animals."
 Column 2, 1910-1960: *SCB*, same issues as for column 1, converted to 1913 dollars.
 1869, 1879 and 1889-1909: Extrapolated from 1910 by John W. Kendrick, *Productivity Trends in the United States*, Table B-I, "net output."
 1870-78 and 1880-88: Interpolated by Strauss and Bean, *Gross Farm Income*, p. 126, Table 61, Calendar year "ideal index" of farm production.
 Column 3: Col. 1 \div col. 2.

TABLE G-10
 RATIO OF FARM TO TOTAL U.S. GROSS PRODUCT, CURRENT
 AND CONSTANT DOLLARS

Calendar Year	Ratio of Farm Gross Product to Gross National Product	
	Current Dollars (1)	Constant (1913) Dollars (2)
1869	.390	.442
1870	.397	.479
1871	.349	.481
1872	.297	.392
